6 Abstract

19

Cloud computing has recently emerged being a compelling paradigm that pertains to 7 managing and delivering services over the web. The particular prevalent problem connected 8 with cloud is confidentiality, security, as well as reliability etc., in which how the cloud 9 provider assures. To recognize this, a novel architecture is usually introduced that will 10 integrates cloud database services and as well executing concurrent operations on encrypted 11 information. Also a new homomorphic encryption algorithm will likely be incorporated to 12 offer confidentiality as well as concurrent execution of various SQL operations. This will be 13 the first option supporting quite a few stributed clienteles to access encrypted cloud 14 databases. One of main thing is that it eliminates advanced proxies in between cloud user and 15 provider. The performance on the architecture is usually lculated by means of theoretical and 16 practical results which are subjected to TPC-C benchmark standard tools for a number of 17 clients as well as network latencies. 18

20 *Index terms*— cloud, security, homomorphic encryptions, confidentiality.

Introduction n a cloud era, critical data is placed in infrastructure of third parties services assuring the protection and confidentiality may be the prior importance. By which the cloud provides as well as the third parties services has the availability of accessing the confidential information from the clients. So the original plain data is available by the trusted parties as well as remaining untrusted context data should be encrypted. There are many solutions ensuring the confidentiality for storage as a service but confidentiality from the dbaas continues to be in naive stage.

27 The architecture design is motivated because of the multiple and independent clients to perform the operations within the secured data because of the SQL statements, which could modify the database structure. Database as 28 a service is an important and operational technique enabling IT providers to provide database functionality being 29 a service to number of consumers. The propose architecture provides the property of making the independent 30 and parallel operations for the remote encrypted database from any geographically located clients, in any 31 unencrypted database setup. In the proposed system we have been not including any Author ? ?: Department 32 of CSE, Sree Vidyanikethan Engineering College, Tirupati, AP, India. e-mails: jagadesh.palle@gmail.com, 33 sivapavan.mr@gmail.com intermediate proxy relating to the client and the particular cloud provider. The Secure 34 database as a service is actually immediately applicable to any DBMS as it doesn't require any modifications for 35 the cloud database. Along with the other part regarding architecture is tailored for the homomorphic encryption 36 37 algorithmic process that provides confidentiality by implementing various computations on data.

A huge set of tests on real cloud platforms elucidates that Secure DBaaS is straight away applicable to any package as a result of it needs no modification on the cloud data services. Other studies where ever the proposed design is subjected to the TPC-C standard benchmark tools for various clients and network latencies shows which the performance of synchronic read and write procedures does not modify Secure DBaaS database structure. Thus suggested architecture provides security by applying the homomorphic encryption on the information of clients along with the response time with the read/write operations may decrease as for the reason that entire database is usually encrypted. Overall the conclusions of paper are crucial because for the first time demonstrates the

45 applicability of encryption to cloud database services in terms of performance and overheads.

46 **1** II.

47 2 Related Work

48 Secure DBaaS gives several unique features that differentiate it from earlier work in the field of security intended 49 for remote databases services.

? It assures files secrecy by enabling some sort of cloud database server to execute concurrency SQL operations
 (not only read/write) over encrypted files.

52 ? It provides the availability, elasticity, and scalability of the original cloud dbaas because it does not require 53 any proxy server.

54 ? Response times are affected by cryptographic overheads for most of SQL operations are masked by network 55 latencies.

⁵⁶ ? It does not involve a reliable proxy because tenant data and metadata saved by the cloud database are ⁵⁷ usually encrypted.

58 Cryptographic systems and secure storage options represent the earliest works in this field. We don't depth 59 the many documents and products (e.g., Sporc, Sundr, and Depot) because they cannot support computations 60 on protected data.

61 L. Ferretti proposed an architecture that reduces the risk for any intermediary part, thus achieving availability 62 and scalability just like that of unencrypted cloud database services. Advantages are Guarantees file consistency in scenarios during which independent clients simultaneously execute SQL requests, and the structure from 63 the database can end up being modified. Reduced isolation quantities for multi-version systems have not 64 been characterized before despite being implemented in several products and the drawbacks are concurrent 65 modifications from the database structure are generally supported but at the expense of higher overhead as well 66 as stricter transaction remote location levels. In that paper, we present Crypt DB because intermediate server 67 68 involving the client and server delivers confidentiality for request that uses DBMSs. Crypt DB's approach should 69 be to execute queries in excess of encrypted data as well as the key that SQL runs on the well-defined set while operators. The benefits are, Crypt DB stops the DBA through learning private files. Crypt DB ensures your 70 confidentiality of logged out users data. Their drawbacks are generally Throughput penalty arises while tracing 71 your database using MYSQL servers is looks like its modest or unassembled. This paper overcomes the issue 72 between a client as well as the server while processing the clients issue request. In that paper we advise, using 73 multiple service providers so that you can store data. This process may use the decomposition algorithm that 74 75 the columns of a database can be split across your server. This algorithm should match the following:

? Privacy constraints should not be violated ? Workload should be reduced Various approaches guarantee 76 77 that database as a service provides clients seamless mechanisms to produce, store, and access their databases 78 in the host site. NetDB2, a database model on-line provides a useful mechanism for organizations to acquire 79 data management like a service. Database as an email finder service makes the benefit of additional overhead of remote access to data, an infrastructure to guarantee data privacy, and program design. Data privacy can be 80 81 achieved in different levels by utilizing encryption techniques with both software and hardware levels. NetDB2 model also performs create/remove furniture, views, triggers, crawls, abstract data varieties, SQL queries, create 82 and call user defined functions and stored procedures, producing and deleting crawls, etc. Some dbms engines 83 offer the chance of encrypting knowledge at the file system level through the alleged Transparent Information 84 Security feature. This feature makes it possible to construct a reliable dbms over untrusted storage. The dbms is 85 trusted and decrypts knowledge before their use. This approach is not applicable to the dbms situation regarded 86 87 by SecureDBaaS. Since we believe that the cloud company is untrusted.

88 The reliance on the trusted proxy in which it allows for the implementation of secure dbaas, and it is applicable in order to multitier world-wide-web applications, which might be their major focus. This causes various 89 drawbacks. Considering that the proxy is actually trusted, its functions are not outsourced for an untrusted 90 fog up provider. The proxy is supposed to always be implemented as well as managed because of the cloud 91 renter. Availability, scalability as well as elasticity of the whole safeguarded dbaas support are then bounded 92 by means of availability, scalability as well as elasticity of the trusted proxy that becomes 1 point involving 93 failure and also a system bottleneck. Given that high availability, scalability as well as elasticity are one of many 94 foremost factors that lead to the adopting of fog up services, this limitation hinders your applicability for the 95 cloud data source scenario. Secure DBaaS solves this challenge by making clients connect directly to the DBaaS, 96 without necessity of any kind of intermediate part and without introducing completely new bottlenecks as well 97 98 as single factors of failing.

99 A new proxy based buildings requiring which any buyer operation should move through one advanced beginner 100 server isn't suitable to help cloudbased situations, in which in turn multiple clientele, typically sent out among 101 various locations, need concurrent use of data stored from the same DBMS. On the other hand, SecureDBaaS sustains distributed clientele issuing self-sufficient and contingency SQL operations towards same database and 102 perhaps to identical data. SecureDBaaS expands our early studies exhibiting that files consistency can be 103 guaranteed for some operations simply by leveraging concurrency isolation mechanisms carried out in DBMS 104 engines, and discovering the lowest isolation level important for those claims. Moreover, we have now consider in 105 theory and experimentally a total set regarding SQL procedures represented by the TPC-C typical benchmark, 106

besides multiple clients and different client-cloud circle latencies that have been never evaluated from the 107 literature. 108

III. 3 109

Motivation 4 110

Sustaining critical data in the hands of a cloud provider is often a challenging one that is certainly associated with 111 secrecy. There exist quite a few encryption techniques now available that provides the particular guarantee of 112 safety measures and availability for data. To provide each of the security features to data there were different types 113 of architectures; algorithms are increasingly being developed and are in naive stage. Feasibility, functionality and 114 performance can be calculated using typical tested like emulab and cloud providers like amazon EC2, windows 115 azure, Xeround, Rackspace etc., IV. 116

Problem Definition 5 117

Today most of the information is being maintained in the hands of cloud providers. But how far the data is 118 secure and available whether the data is in use, in motion and at rest. This is a critical phenomenon and there 119 exists several possible solutions too. Also how securely cloud databases can be accessed. 120 V.

121

Problem Statement 6 122

Secure DBaaS is made to allow numerous and separate clients to connect to cloud without intermediate server. 123 Data and also metadata are generally encrypted just before upload towards the cloud. Multiple cryptography 124 techniques are widely-used to transform plain word into encrypted data. Table titles and the column names 125 can also be encrypted inside cloud database using safety scheme. The device supports geographically spread 126 clients to connect directly a great encrypted cloud database. The client can execute concurrent query processing 127 encrypted sources. Homomorphic encryption operations like RSA, ElGamal, Pailler systems are widely-used in 128 the machine. Concurrent data and data structure changes are allowed for the cloud sources. The following 129 problems are generally identified through the existing method. 130

- ? Database structure modification increases the computational overhead 131
- ? Data integrity verification is not performed 132
- ? Access control mechanism is not provided? Query submission is not secured VI. 133

7 **Problem Formulation** 134

With cloud research technology, there were plenty of important policy issues may include like privacy, secrecy, 135 anonymity, government surveillance, stability etc., Of these entire most crucial one will be security, through which 136 how the cloud provider assures. Generally cloud computing features different class of customers that features 137 138 academicians, everyday users and also enterprises etc., in which in turn their motivation is always to move about the cloud regarding deploying software, managing assets etc. Security standpoint is different perspective 139 regarding for different consumers. Suppose regarding enterprises high performance may become criteria whereas 140 for academicians it can be on the performance regarding computing. Like this several issues occur in the cloud. 141

VII. 8 142

9 Architecture Design 143

The architecture layout of Secure DBaaS is made up of one or more client devices with SecureDBaaS installed 144 and also cloud database. The below Fig. 1 gives entire architecture. This certain client is likely for the text 145 of anyone to this particular cloud dbaas to be able to perform SQL operations. To combat the confidentiality 146 troubles, many cryptographic strategies are widely-used to convert plaintext data to encrypted variety for storing 147 inside cloud database. The architecture consists of five types of information. Such as Plain data: the informative 148 content provided by the client users. 149

- Encrypted data: the encrypted data that is stored in the cloud database. 150
- Plain metadata: all the information required by the clients to manage encrypted data on the cloud database. 151 Encrypted metadata: the encrypted metadata that is stored in the cloud database. 152

Master key: the encryption key of the encrypted metadata. This key is distributed to all the clients. Here 153 we assume that tenant firm acquires the cloud database service from untrusted dbaas provider. The tenant 154 155 then deploys a number of machines and installs the Secure DBaaS consumer on each of them. This consumer 156 allows the user to touch this cloud dbaas to manage it, just read and compose data, as well as to build and change the repository tables after creation. We assume the identical security model that is commonly adopted 157 where tenant users usually are trusted, the circle is untrusted plus the cloud provider is honest-but-curious, cloud 158 service operations are accomplished correctly, however tenant info confidentiality threat. The info managed 159 through Secure DBaaS includes plaintext data, encrypted data, metadata, and encrypted metadata. Plaintext 160 data incorporate information that your tenant wants to store and process remotely inside cloud dbaas. To stop 161

an untrusted impair provider by violating confidentiality of tenant data located in simple form, Secure DBaaS 162 switches into multiple cryptographic approaches to transform plaintext data into encrypted tenant data and 163 encrypted tenant data set ups because even the names from the tables and of these columns has to be encrypted. 164 Secure DBaaS consumers produce also a set of metadata composing of information forced to encrypt decrypt data 165 as well as other administration info. Even metadata usually are encrypted and stored inside cloud dbaas. Secure 166 DBaaS moves away from existing architectures which store just tenant data inside cloud repository, and spend 167 less metadata inside client appliance or separated metadata involving the cloud database along with a trusted 168 proxy. When contemplating scenarios exactly where multiple consumers can access the identical database at the 169 same time previous solutions are quite inefficient. Solutions depending on a trustworthy proxy tend to be feasible; 170 nonetheless they introduce a head unit bottleneck which reduces access, elasticity and scalability involving cloud 171 repository services. Secure DBaaS proposes a new approach exactly where all data and metadata usually are 172 stored throughout the cloud database. Secure DBaaS consumers can retrieve the mandatory metadata from 173 the untrusted repository through SQL statements, so which multiple instances of the Secure DBaaS consumer 174 can access to the untrusted impair database independently while using the guarantee from the same access and 175 scalability properties of typical cloud dbaas. Encryption strategies for tenant data and modern solutions intended 176 for metadata administration and safe-keeping are explained. 177

178 **10** VIII.

179 11 Problem Solving a) Homomorphic Encryption Applied to 180 Cloud Security

When the data transferred in the cloud we employ standard encryption approaches to secure the actual operations 181 along with the storage from the data. Our essential concept seemed to be to encrypt the data before deliver it to 182 the Cloud provider. But a final one should decrypt info at each and every operation. The client will likely need to 183 provide the actual private key to the server (Cloud provider) to decrypt data before performing the calculations 184 required, that may affect the actual confidentiality and privacy regarding data stored from the Cloud. Here 185 we execute operations on protected information without decrypting them, which may provide the exact same 186 results after calculations like we have worked on the raw data. Homomorphic Encryption programs are used to 187 accomplish operations on encrypted data without knowing the private key (without decryption), the customer is 188 the only real owner of the secret key. 189

Def.: An encryption is homomorphic, if from Enc(x) and Enc(y) it is possible to compute Enc(f(x, y)), where f can be: $+, \times, ?$ and without using the private key .One of the Homomorphic encryption we recognize, according to the operations that enables to evaluate on information, the additive Homomorphic encryption (only additions of the data) could be the Pailler and Goldwasser-Micalli cryptosystems, and the multiplicative Homomorphic encryption (only products on data) could be the RSA and El Gamal cryptosystems. Suppose Ek is an encryption algorithm with key k.

Dk is a decryption algorithm with key k. We identify the SQL operations in Secure DBaaS simply by considering an initial simple scenario by which we assume that the cloud repository is utilized by a single client. Our goal suggestions to highlight the principle processing measures; we usually do not think about performance optimizations and also concurrency.

The first connection on the client with the cloud DBaaS is for authenticated functions. Secure DBaaS utilizes 200 standard authentication and also authorization mechanisms provided by the authentic DBMS server. After the 201 authentication, a individual interacts with the cloud database over the Secure DBaaS purchaser. Secure DBaaS 202 analyzes the original operation to be able to identify that tables could happen and to be able to retrieve their 203 metadata from your cloud repository. The metadata are decrypted over the master key and their particular 204 information is employed to translate the plain SQL into a query which operates for the encrypted repository. 205 Translated operations are then executed with the cloud database above the encrypted data. Because there can 206 be a one-to-one messages between Plaintext and encrypted text, it may be possible to prevent a reliable database 207 individual from being able to view or editing some renter data simply by granting restricted privileges in some 208 furniture. User privileges might be managed directly with the untrusted and also encrypted cloud database. The 209 outcomes of the particular translated dilemma that contains encrypted renter data and also metadata tend to 210 be received with the SecureDBaaS purchaser, decrypted and also delivered towards the user. The complexity on 211 the translation process is dependent upon any type of SQL affirmations depends on the type of SQL statement. 212

²¹³ 12 d) Concurrent SQL Operations

The support to concurrent delivery of SQL claims issued by numerous separate clients is unquestionably one of the most critical advantages of Secure DBaaS regarding state-of-the-art solutions. Our architecture should guarantee consistency among protected tenant data and protected metadata because broken or out-of-date metadata would prevent clients from decoding protected tenant data producing lasting data losses. A rigorous analysis of the probable problems and answers linked to concurrent SQL procedures on protected tenant data obtainable in the web extra material. Here, we remark the importance of unique two classes of claims that are reinforced by Secure DBaaS: SQL procedures perhaps not producing improvements to the database structure, such as for 221 example for instance read, create, and update; procedures involving variations of the database structure through

development, removal and adjustment of database tables. In cases known with a fixed database structure, Secure DBaaS allows clients to concern concurrent SQL instructions to the protected cloud database without presenting

any new consistency problems regarding unencrypted databases. After metadata collection, a plaintext SQL

order is translated in to one SQL order running on protected tenant data. As metadata don't modify, a consumer

may read them when and cache them for further uses, hence increasing performance. Secure DBaaS is the first

architecture that allows concurrent and consistent accesses even when you can find procedures that might change

the database structure. Such cases, we have to guarantee the consistency of data and metadata through solitude

229 degrees, like the photo solitude that people show may benefit most consumption scenarios.

230 **13 IX.**

231 14 Experimental Results

We display the applicability of Secure DBaaS to various cloud dbaas alternatives by employing and managing protected database procedures on emulated cloud infrastructures. The current edition of Secure DBaaS prototype supports Postgre SQL, My SQL, and SQL Server relational databases. As an initial result, we could discover that porting Secure DBaaS to various DBMS requires modest improvements related to the database connector, and small adjustments of the database.

We carry out a group of tests that assesses the performance and the overheads of our prototype. We utilize 237 the benchmark performance tools like Dell benchmark factory, Monyog, Hammer DB that provide us a managed 238 atmosphere with many machines, ensuring repeatability of the tests for the variety of situations to take into 239 account in terms of workload types, quantity of clients, and network latencies. Because the workload model for 240 the repository, we reference the TPC-C standard. The dbms machine is MYSQL 5.6 used on an Intel processor 241 having 8 GB of RAM. Clients are connected to the machine through a LAN, wherever we can present arbitrary 242 system latencies to emulate WAN connections which can be normal of cloud services. The studies evaluate the 243 expense of encryption, examine the reaction times of simple versus secured repository procedures, and analyze 244 245 the effect of system latency. We consider two TPC-C certified databases with 10 warehouses that have exactly 246 the same quantity of tuples: simple tuples include 1,046 MB information, while Secure DBaaS tuples have size equal to 1024 MB as a result of encryption overhead. Both databases use repeatable study (snapshot) isolation 247 248 stage.

To evaluate response times, the customer steps the performance times of the 44 SQL commands to the TPC-C benchmark. Response times are plotted on the histogram of the Fig. 3 that has a logarithmic Y-axis. TPC-C procedures are grouped on the foundation of the school transaction: Order Status, Stock Level, Payment, and New Order, Delivery. Out of this determine, we are able to enjoy that the response time is less than 3 ms for many procedures, and under 1 ms for nearly all procedures.

254 15 Global

255 16 Conclusion

We propose an impressive architecture that guarantees confidentiality of data in public cloud databases. Unlike 256 state-of-the-art strategies, our solution doesn't rely on an intermediate proxy that people think about a simple 257 level of disappointment and a bottleneck decreasing supply and scalability of normal cloud database services. 258 A big part of the research contains alternatives to guide concurrent SQL operations (including claims adjusting 259 the database structure) on secured knowledge given by heterogeneous and probably geographically distributed 260 clients. The proposed architecture doesn't need changes to the cloud database, and it's instantly appropriate 261 to current cloud dbaas. We find no theoretical and sensible limits to extend our treatment for other tools and 262 to incorporate new encryption algorithms. Its price observing that experimental benefits based on the TPC-C 263 benchmark standard shows that the performance effect of information encryption on result time becomes minimal 264 because it's negligible by network latencies that are typical of cloud scenarios. Specifically, concurrent study and 265 create procedures that maybe not change the framework of the secured database trigger minimal overhead. XI. 266 267
