# A Novel Erasure Coding based on Reed Solomon Fault Tolerance for Cloud based Storage Satyanandam.N<sup>1</sup> and Ramprakash Kota<sup>2</sup> <sup>1</sup> ANU Received: 8 December 2015 Accepted: 3 January 2016 Published: 15 January 2016

#### 7 Abstract

In the recent years growth in usage of Erasure codes for fault tolerance is been observed. The 8 growth in distributed storage solutions is the root cause of this growth. Multiple research is 9 been carried out to propose the optimal fault tolerance solution for distributed storage 10 solutions. However the recent storage solutions have shown a migration towards to the cloud 11 based storage solutions. The growth of cloud computing and the benefits to the customer is 12 the core of this migrations. Thus the applications managing the storage solutions have also 13 updated with the demand. Hence the recent researches are driven by the demand of optimal 14 fault tolerance solutions. Here in this work we propose an optimal erasure code based fault 15 tolerance solution specific for cloud storage solutions. The work is been considered for 16 commercial cloud based storage solution. The final outcome of this work is improvement on 17 Bit Error Rate for the proposed Novel Erasure Coding based on Reed Solomon Fault 18 Tolerance for Cloud based service. 19

### 22 1 INTRODUCTION

23 Author ? : Senior System Architect, USA, Research Scholar, Department of CSE, ANU, India. e-mail: 24 ramprakash.kota@gmail.com Author ? : Director, Sri Prakash College of Engineering (SPCE), Tuni, India. e-mail: dr.amjanshaik@gmail.com loss. The type of failure can be not having control on getting disk sectors 25 corrupted or the entire disk is becoming unusable. The storage services have some self-protecting mechanism 26 as extra-corrective information that can detect changing of few bits from the original data and can still retrieve 27 the originally stored data. However there are situations when multiple bits change unexpectedly, then the self-28 protecting mechanism detects that as hardware failure and storage devices become un-usable. This situations 29 lead to loss of data [1] [2]. 30

To handle these types of anomalies, the storage systems depend on Erasure codes. The Erasure code deploys 31 the mechanism of assured redundancy to overcome the failures. The most generalized way of implementing this 32 mechanism is replication of data over multiple locations. The most popular and simplest is Redundant Array of 33 Independent Disks or RAID. In that the most basic version of these implementations is RAID -1, where every 34 35 data byte is stored in at least two parallel disks. This way the failure may not lead to loss of data as long as 36 a replicated copy of the data is available. This mechanism is easy to achieve, however this leads to many other 37 overhead factors like cost of storage. The storage cost should be at least double than the actual cost. Moreover 38 in any case if both the storage device fails then the complete solution becomes unusable.

In the other hand, there are more complex solutions under Erasure methodologies such as wellknown Reed-Solomon codes. Reed-Solomon code can overcome high level failures with little less extra storage. These codes provide high level of failure tolerance with reduced cost [3].

In communication systems the Erasure coding is similar to Error Correcting Codes or ECC. Here the Erasure coding solves the similar types of problems but addresses very different types of problems. In massage communication, the error is caused by changing bits of the data. Here is the different lie between Erasure and
message communication as the location of the changing bits is unknown. Hence application of Erasure is restricted
??3] [11] [12].

The rest of the work is organized such that in Section II we discuss the fault tolerance mechanisms for Non 47 -Cloud but distributed storage systems, in Section he tremendous growth in cloud storage services and the fact 48 that is has reached to a point where loss of data due to failure is expected. The real challenge is thrown to the 49 designer of the storage solutions for cloud services to protect the data loss during failure. The core technology 50 behind protecting data during loss is Erasure coding. Previous works demonstrates the use of Erasure coding for 51 the last two decades. However the true understanding of Erasure and effective use of Erasure Coding is never 52 been discussed based on different cloud service provider. 53 Thus this leads to confusion in solution designer and developer community. Hence in this work we focus on 54

Thus this leads to confusion in solution designer and developer community. Hence in this work we focus on fundamental understanding of Erasure Coding, Comparisons and analysis of Erasure performances on multiple cloud storage service providers [1].

The storage systems on cloud came a long way in terms of capacity and latency time improvement. All the storage hardware types are commonly failing to protect data during failures and unable to restrict data T III we realise the Reed Solomon Fault Tolerance mechanism, in Section IV we propose the Novel Erasure Coding based on Reed Solomon Fault Tolerance for Cloud Based Storage, in Section V discuss the Erasure Coding mechanisms for Cloud Storage Service Providers, in Section VI we produce the results obtained for the proposed scheme and in Section VII we conclude.

# <sup>63</sup> 2 II. FAULT TOLERANCE MECHANISMS FOR NON <sup>64</sup> CLOUD DISTRIBUTED STORAGE

<sup>65</sup> The standard fault tolerance mechanism depends on the erasure codes [4]. The basic mechanism can be <sup>66</sup> understood if we assume a collection of n disks are partitioned into k disks. Hence there will be m disks <sup>67</sup> which will hold the coding information as 1 r n i i m n k  $\langle = = ? ? ? . Eq 1$ 

68 Where r denotes number of k multiple of disks The basic interpretation of the erasure codes can be understood 69 as each disk must hold a z bit word to represent the customer data. If we denote them with d then the total set 70 of codes for k number of disks are considered as  $2 \ 3 \$ , .... k z z z z ?.Eq 2

Also we consider the codes stored on each every m disk with c, and then the total representation is considered as  $1\ 2\ 3$ , .... k c c c c ?.Eq 3

The coding and the customer data should a linear combination and can be represented as 0 1,0 0 1, 1 1 1 2,0

74 02,11,00,**11** ()k k k m m m k k c a z a z c a z a z c a z a z ????? = + + = + + = + + ?.Eq 4

The coefficients "a" are also z bit words. Encoding, therefore, Simply requires multiplying and adding words, and decoding involves solving a set of linear equations with Gaussian elimination or matrix inversion.

Furthermore, we understand the most popular coding techniques here.

## 78 3 a) RAID-4 and RAID-5

The RAID -4 and RAID -5 [5] are the simplest form of the erasure codes explained in this work earlier. RAID
-4 and RAID -5 differs from the basic framework as it employs different arrangements of data replication.

The RAID is a modification to MDS code where m=1 and z=1. The basic coding depends on a bit noted as p, where 0 1 1 ... k p z z z ? = ? ? ?  $\therefore$ Eq 5

In case of any bit changing, the XOR code will identify it for the surviving code.

## <sup>84</sup> 4 b) Linux RAID-6

The Linux system RAID -6 [6] [9] is considered as additional support to RAID -4 and RAID -5 as it uses an alternative disk under the framework. This framework proposes an alternation to the MDS as considering the code to be stored in two disks as m=2. Hence the formulation is too simple by using an XOR code:1 2 1 2

# <sup>89</sup> 5 2() ... 2 ()

90 k k k p z z z q z z z = ? ? ? = ? ? ? .Eq 6

Here the codes called p and q will be stored on alternative disks to ensure the Erasure code to protect the data loss.

## 93 6 c) Array Codes

 $_{94}$  The framework is called Array code as it is implemented using r X n array of customer data. In this framework the

<sup>95</sup> customer data will be stored with the arrangements as Figure -1. The array code with the following parameters: <sup>96</sup> k=4, m=2 (RAID-6), n=k+m=6, r=4, z=1.

### <sup>97</sup> 7 d) Non-MDS Codes

The Non-MDS codes do not allow replication of m storage devices to achieve optimal fault tolerance. The replication of storage devices containing the code is higher than the other frameworks. However the efficiency provided by the Non-MDS codes compared to other frameworks in terms of performance is high.

101 Hence we compare all the types of code frameworks here.

# 102 8 III. UNDERSTANDING REED-SOLOMON ERASURE

The most important factor that makes Reed-Solomon framework to implement is the simplicity. Here in this work we consider the scenario to compare the performance of Reed -Solomon and Proposed Encoding technique [7] [8].

108 CCCCC=? ?Eq 8

Where C is the collection of Checksum devices The checksum devices will hold the calculated values from each respective data storage devices.

111 The goal is to restore the values if any device from the C collection fails using the non -failed devices.

The Reed -Solomon deploys a function G in order to calculate the checksum for every device in C. Here for this study we understand the example of the calculation with the values as K = 8 and L = 2 for the devices C 1 and C 2 with G 1 and G 2 respectively.

The core functionalities of Reed -Solomon is to break the collection of storage devices in number of words. Here in this example we understand the each number of words is of u bits randomly. Hence the words in each device can be assumed as v, where v is defined as 8 1 (

- 118 ). . bits word v nbytes byte u Bits? ? ? ? = ? ? ? ? ? ? ? ? ? Eq 9
- Furthermore, v is defined as 8n V u = 2Eq10

Henceforth, we understand the formulation for checksum for each storage device as .( , , ... )i i k C W D D D 121 D = 2Eq 11

Where the coding function W is defined to operate on each word After the detail understanding of the Erasure fault tolerance scheme, we have identified the limitations of the applicability to the cloud storage services and propose the novel scheme for fault tolerance in this work in the next section.

# <sup>125</sup> 9 IV. PROPOSED NOVEL FAULT TOLERANCE SCHEME

With the understanding of the limitations of existing erasure codes to be applied on the cloud based storage systems as the complex calculations with erasure codes will reduce the performance of availability measures significantly. Thus we make an attempt to reduce the calculation complexities with simple mathematical operations in the standard erasure scheme.

The checksum for storage devices are considered as C i from the Eq 11. We propose the enhancement as the following formulation for checksum calculation:1 2 3 1**2 3** 

132 .( , , ... ) ( ... )i i k i k C W D D D D W D D D D = = ? ? ? ?Eq 12

Here the XOR operation being the standard mathematical operation most suitable for logical circuits used in all standard hardware makes it faster to be calculated.

The proposed matrix will be stored on one of the devices and will be recalculated only once. As the modified checksum formulation is an XOR operation, thus which will automatically notify in case of any change.

The comparative simulations is also performed in this work and the enhancement in the performance is also been exhibited.

# 10 V. ERASURE CODING MECHANISMS FOR CLOUD STORAGE SERVICE PROVIDERS

As the most noted fault tolerance framework is the Erasure codes, hence we understand the application of Erasure
 codes on various cloud storage service providers [10].

## <sup>145</sup> 11 a) Erasure on Microsoft Windows Azure

Microsoft Windows Azure employs a Local Reconstruction Code or LRC to be implemented using Reed -Solomon
Code. The LRC is shorter code, which is robust and portable to implement and store. Here we understand the
application framework in detail:

We assume there are 6 data segments and 3 parity segments. Here the 3 parity segments are computed from 6 data segments stored in distinguished 9 disks. During failure any segment can be used for reconstruction. As the data and code is distributed over 9 segments, hence all the 9 segments need to be used for reconstruction. Azure define the cost of reconstruction is equal to number of data segments required for reconstruction. Hence

in this case the total reconstruction cost is 6. However the main purpose of LRC is to reduce the reconstruction

154 cost by calculating some of the codes from the local data segments. Hence to follow the same logic we have now

4 parity codes. Two of the parity codes are generated from all the data segments and should be kept globally. In

the other hand the remaining two parity codes are computed from each storage data segment groups and should be kept locally [Figure ??2].

### <sup>158</sup> 12 Figure 2 : LRC Computation

Here the construction of LRC adds an additional parity code into the Reed -Solomon code. Hence it may appear
as addition load on the computation, however this computation does not execute during the conventional tractions
of data.

### <sup>162</sup> 13 b) Erasure on Amazon S3

The basic implantation of fault tolerance of Amazon Simple Storage Service or S3 depends on the RAID framework. However rather than depending only on the storage providers, Amazon also recommends to employ application based fault tolerance mechanism. Hence this frame work should be considered as RAID -Application

based framework. This is very much similar to Service Oriented Architecture or SOA model for RAID.

167 The fault tolerance mechanism for Amazon S3 has three major components in the framework [Figure ??3]:

### <sup>168</sup> 14 c) Erasure on Google File Systems

The File System in Google employs an essential high load data processing and storage solutions on public storage systems. The most crucial recovery factor relies on the Google's specific algorithms using constant monitoring, replication management, automatic and chunk recovery.

- Hence we understand that most of the cloud service providers use Erasure codes for their storage solutions with modifications leading to service and cost benefits.
- 174 VI.

### 175 **15 RESULTS**

The proposed fault tolerance scheme is been simulated and tested against the basic erasure fault tolerance scheme with the signal to noise ratio with Bit Error rate.

The first simulation results is the basic erasure fault tolerance code shows the bit error rate for each signal to noise ranging from o to 15 decibel. The simulation results is also been generated using MATLAB simulation to observe the improvement <sup>1 2</sup>
