9 The Mobile Ad hoc Networks playing critical role in network aided communication

¹⁰ requirements. The features such as ad hoc and open architecture based connectivity and node

¹¹ mobility are elevating the mobile ad hoc networks as much as feasible to deploy and use. The

¹² direct communication between any of two nodes in this network is possible if target node is in

the range of source node. If not, the indirect communication took place, which is usually

¹⁴ referred as multi hop routing. The multi hop routing occurs as either a unicast model (one

¹⁵ source node to one destination node), multicast model (one source node to multiple

¹⁶ destination nodes) or multiple casting (manifold unicast routing). In these routing strategies,

¹⁷ provision of service quality in multi hop routing is a challenging task. The optimal quality of

18 service in routing, magnifies the delivery ratio, transmission rate, network life span and other

¹⁹ expected characteristics of the ad hoc routing. Among the quality service provision factors

 $_{\rm 20}$ $\,$ minimal energy conservation is prime factor, which is since the nodes involved in routing are

²¹ self-energized and if discharged early then the route will be destructed that causes

discontinued routing. The energy consumption is more specific in multicast routing, hence it is
 grabbing the more attention of the current research contributions.

Index terms— multicast routing protocols, mobile ad hoc network (manet), energy efficient routing. tree based multicast route, mesh based multicast route, zone bas

27 1 Introduction

obile ad hoc networks (MANET) [1] is one of the critical class of network aided distributed communication. The 28 features such as dynamic connectivity, less infrastructure ability of node mobility enables to establish network 29 aided communication in civilian environments such as army communication in battle grounds, natural calamities 30 handling and social media sharing between hand held and mobile devices. The direct communication between 31 any devices of the MANET is possible only if receiver is in the range of sender. If receiver is not in the range 32 33 of the sender, then the route can be established between sender and receiver by using the intermediate devices 34 called nodes. The phenomenal growth in computer aided network communication demands instant access to 35 any network in order to exchange digital data. The video conferences, digital data sharing between students in academic strategies, service search and information sharing in business enterprises and social media are the 36 few examples to justify the demand of ad hoc network strategies. The constraints such as indefinite node 37 density of a network, unpredictable mobility of the nodes, and other operational factors of a node such as egress 38 and ingress capacity, residual energy levels compromised behavior of the nodesevincing that intermediate nodes 39 selection to establish route between source and destination is a challenging task. Though the many contributions 40 found in contemporary literature to establish optimal routes, they limited to one or two quality factors. Hence 41

5 CONTEMPORARY AFFIRMATION OF BENCHMARKING QOS MULTICAST ROUTING PROTOCOLS

42 the quality provisioning in route discovery is still an open issue for current research domain. Multicasting is

43 significantly sensitive to discover optimal routes, which since the load of transmission is significantly high and 44 often intermediate nodes are necessarily transmit data to multiple nodes in order to transmit data to multiple

target nodes. Hence the node life span is most critical to retain the multicast route to complete data transmission

between one source to many destination nodes. Hence, this manuscript reviewed contemporary literature on

47 energy efficient multicast routing strategies.

The paper is organized as follows. Section 2 describes nomenclature of the multicast routing strategies. Section

3 is the contemporary affirmation of the benchmarking energy efficient multicast routing models fund in recent
 literature. Section 4summarizing the manuscript contributions.

51 **2** II.

⁵² 3 Nomenclature of the Multicast

Routing Strategies based on service provision strategies such as reliability, bandwidth usage, delay, bandwidth 53 delay and power aware or energy efficient. The tree based multicast routing protocols of these categories are 54 55 subcategorized as source-rooted and core-rooted schemes according to the roots of the multicast trees. The source 56 node acts as root node of the tree and maintains the topology related information and addresses of all nodes 57 involved in multicast route, hence the model is evincing the constraints such as process, route maintenance and 58 traffic overheads. The other category of tree based multicast routing models are core-rooted models, which is the set of subtrees and each sub tree behaves as source rooted trees. Each subtree is formed by a node involving 59 multicasting as root node. The core-root tree based multicast routing strategies are optimal than source-root tree 60 based multicast routing strategies but route stability is a questionable factor. Though the tree based multicast 61 models are is establish but frequent destruction of the route due to node mobility is quite often that abandons 62 the data transmission till the reformation of the tree happens. 63 The sub categories of the mesh based multicast routing models are also based on either core or central nodes, 64

which are as similar as source and core root based multicast trees. But mesh based multicast routing models are node mobility resistant. Hence the route destruction due to node mobility is least significant in mesh based ulticast routing models.

The multicast models of the zone based topology partitions the network region as virtual zones. Further the nodes of each zone are used to core-root tree or core-point mesh. The node that considered as core-root or core-point is the zone head. The inter zone communication is done through the zone heads. The considerable advantage of the zone based multicasting models is, the node mobility needn't be tracked, instead, notifying zone change of the node is sufficient. The visible constraints of these zone based multicasting are overhead of zone formation, route discovery and route maintenance.

The hybrid models of multicast routing protocols are the combination of either all of tree, mesh and zone topologies or any of two.

The other considerable category of multicast routing protocols are hierarchical models. This category is often fall under hybrid models. This multicast routing protocols are set of connected multicast routing protocols of one or more of the types called tree, mesh and zone based topologies. The constraints specific to these topologies can be evinced even in hierarchical models. The classification of the multicast routing strategies based on the tree, mesh, zone and hybrid topologies explores issues in multicast routing specific to reliability, delay, bandwidth usage, bandwidth delay, link stability and energy usage.

The context of this manuscript is reviewing energy efficient multicast routing protocols, hence the benchmarking energy efficient multicast routing protocols that fall in either of the category explored and found in contemporary literature are informed in detail in following section.

⁸⁵ **4 III.**

⁸⁶ 5 Contemporary Affirmation of Benchmarking qos Multicast ⁸⁷ Routing Protocols

88 This section explores the some of the benchmarking energy efficient multicast routing models found in 89 contemporary literature.

90 model is to minimize bit level energy consumption. In regrad to this network coding is adapted to in multicast 91 routing. The empirical analysis of the model claimed the significance of the network coding to achieve bit level 92 energy consumption to be minimal and construction of multicast tree that consumes overall energy as much 93 as low. The considerable constraint is that if transmission distance increased between nodes then the energy 94 consumption is complemented and often route destruction evinced if noise found during transmission.

Guo et al., [3] proposed an energy efficient multicast routing model for Wireless ad hoc networks with Omni antenna based neighbor node communication strategy. In case of source initiated multicast traffic, power saving capability achieved through the usage of adaptive antennas. In order to select nodes those transmit data as radio frequency with minimal usage of the energy, the mixed integer linear programming (MILP) is adapted here in this ⁹⁹ model. The experimental study noticed that, this model is highly adaptable only for low and midsize networks ¹⁰⁰ to achieve minimal energy consumption. The constraints observed for the model [2] even found in this model.

A distributed minimum energy multicast model [4] proposed for mobile ad hoc networks with nodes using 101 102 Omni directional antennas. The objective of the proposal is to minimize the energy usage for radio frequency transmission. In order to build an energy efficient multicasting tree, this model is considering the factors 103 such as managing distinct levels of energy usage, balancing the flooding in multicast tree and multicasting 104 tree maintenance. The overall routing process is in two dimensions and those are achieving minimal energy 105 consumption and continuous reformation of the multicast tree to avoid the route failure due to node mobility. 106 The energy consumption in regard to radio frequency (RF) transmission is estimated by the distance between 107 source and destination Omni directional antennas. The experimental study indicating that the model is out 108 performed in Manets with low mobility nodes. The significant constraint of the model is that it is not considering 109 the route lifespan (residual energy is not assessing), which causes often route destruction, also not considering 110 the signal to noise ratio, hence the energy saving is not optimal if noise found in RF transmission medium. 111

Li et al., [5] proposed an Energy efficient multicast routing in ad hoc wireless networks that equipped with Node-112 Join-Tree, Tree-Join-Tree and directed Steiner tree based multicast tree building algorithms. An approximation 113 algorithm is used to overcome the NP-Hard problem of the multicast tree formation [6]. The greedy approaches 114 NJT (Node-Join-Tree) and TJT (Tree-Join-Tree) are used to perform optimal node joins to build multiple sub 115 116 trees and optimal sub tree joins to build multicast tree respectively. Each neighbor node verification and each 117 sub tree verification are the critical computational constraints observed in NJT and TJT respectively. In order to overcome this Steiner tree method is used to achieve greediness in node verification and subtree verification in 118 respective NJT and TJT. The empirical study evincing optimal performance of this model in Manets with nodes 119 with less transmission distance between them. The constraints noticed for models [2] [3] are noticed even for this 120 model. 121

Gua et al., [7] extended their earlier contributions ??3][4] with basic energy-efficient multicast (BEEM) and 122 distributed maximum lifetime multicast (DMLM), for increasing the lifetime of the network. Distinct energy usage 123 scheme is adopted from [4], and node location identification is done by positioning system. The experimental 124 study compared the performance of BEEM, DMLM and ODMRP in the context of maximal lifespan of the 125 network. The comparison evinced that DMLM increased the network lifespan through minimal energy usage 126 that compared to BEEM and ODMRP and the network lifespan observed under BEEM is much better than the 127 ODMRP. The computational and process control overhead also found high in the order of DMLM, BEEM and 128 ODMRP, which is considerable constraint of the proposal. 129

Shafigh et al., [8] proposed a mesh based multicast routing that selects nodes based on their residual energy. 130 In order to this the proposed model is using fuzzy reasoning to segregate nodes with low residual energy and high 131 residual energy. The proposed models is on demand multicasting model that uses fuzzy reasoning to select optimal 132 nodes in order to build mesh based multicast route. The fitness function of the fuzzy logic is assessing the residual 133 energy levels of the nodes capable to involve in route establishment. The empirical study compared the values 134 obtained for metrics (such as PDR, control overhead, end-to-end delay) with the values obtained for ODMRP. 135 which are evincing the phenomenal advantage of this model over ODMRP. The constraints observed are downfall 136 in packet delivery ratio and energy usage is complimented against increase in control packet transmission, which 137 is specific to dense networks. 138

Xiang et al. [9] proposed a multicast routing protocol, which is labeled as efficient geographic multicast protocol. This protocol builds zone based bidirectional multicast tree that dilutes the complexity of route discovery and maintenance. In order to this the overall network range is partitioned into virtual zones such that direct communication between any two nodes in a zone is possible. Each zone is equipped with a zone head and if node want to communicate to a node that exists in other zone then the source node seeks zone head role in order. Since the data transmission is zone level but node level, hence route maintenance is phenomenally very low, since the protocol rather monitoring the node mobility, it handles the zone

¹⁴⁶ Global Journal of Computer Science and Technology

Volume XVI Issue IV Version I () change of the nodes due to their mobility. The transmission over head is shared between all member nodes of the zone, hence transmission overhead also be found very low. The empirical study that compared PDR, control overhead and delay observed for this protocol with other benchmarking model called ODMRP and SPBM [10]. The empirical study results evincing that this model performance is optimal than other two. The minimal energy consumption and maximal residual energy are not considered to select a zone based multicast tree, which is a significant constraint to achieve maximum network lifespan.

Tavli et al., [11] devised a cross layer architecture based protocol for multicasting with minimal energy 153 154 consumption, which is using time reservation strategy in multicasting. This protocol also balancing the other QoS 155 factors that includes spatial reuse. This architecture used in this protocol is the combination of multicast mesh and multicast tree structures, where the multicast tree is active and that surrounded by the passive multicast 156 mesh. The passive multicast mesh helps to handle the broken links in active multicast tree efficiently. This 157 protocol is an extension to the earlier model called multi hop time reservation using adaptive control for energy 158 efficiency [12]. This model switches idle nodes to sleep mode and also surpasses the recurrent data transmissions in 159 order to achieve minimal energy conservation. The experimental study evincing the minimal energy consumption 160

and delay that compared to other benchmarking model called ODMRP [13]. The considerable constraint this model is complex cross layer architecture.

Fareena et al [14] proposed a multicast routing model that limiting the overall energy consumption by selecting 163 nodes based on their mobility speed and direction. This is a cross model of mesh and tree architectures. The 164 density of neighbor count also considered in order to select nodes for multicast route building. The metrics node 165 mobility speed and direction, neighbor count and residual energy of each node are used as critical factors by 166 this model to devise energy efficient multicast route. Switching the idle nodes into sleep state is also boosting 167 this model to minimize the energy consumption. The empirical study signifies that the model is optimal as the 168 packet delivery ratio is high, energy consumption and end-to-end delay is low that compared to the ODMRP. 169 The constraints are, control flow overhead and process overhead. The overall energy consumption observed for 170 data packets and control packets transmission is not optimal. 171

Nasab et al. [15] proposed a multicast routing strategy to achieve minimum energy consumption. The devised 172 model is using PSO (particle swarm optimization) [16] technique to discover the route with maximum residual 173 energy, minimal energy consumption and end-to-end delay. The initial multicast tree that includes all nodes in 174 the network is built by prims algorithm and further optimal multicast tree is discovered by applying PSO. The 175 nodes involved in initial tree are considered as particles with the properties called mobility speed, position and 176 direction of mobility. The PSO traverse these particles in order to select qualified particles. Further the optimal 177 178 nodes are being selected from these qualified nodes through the fitness function, which is assessing the node 179 fitness by their residual energy levels, energy consumption ratio. The experimental study evinced that the PSO model is the best fit model to derive energy efficient multicast tree that compared to traditional GA approach. 180 The computational overhead observed for PSO is considerable constraint of the model, which is also lagging to 181 achieve energy efficiency in noisy channels (signal to noise ratio is low in discovered multicast tree). Varaprasad 182 et al., [17] proposed a multicasting protocol that aimed to achieve maximum link stability and minimal energy 183 consumption. Tis proposed model relied on two factors called residual energy of the battery and maximal relay 184 scope. The establishment of route with the nodes having high residual energy and high relay capacity evinced 185 reliable communication. This model is not considering the minimizing the energy consumption to enhance the 186 network life span, which is found to be critical constraint of this model and other constraint is process load due 187 to additional control traffic. 188

Lu et al., [18] proposed a multicast routing model, which is to achieve minimal energy consumption and 189 minimal end-to-end delay. The route discovery strategy is an evolutionary model that uses genetic algorithm 190 in route selection. In order to obtain the optimal multicast tree path, the proposed model is applying genetic 191 evolutions on possible multicast trees discovered in route request phase. The cost function estimating the energy 192 consumption ratio and end-to-end delay in order to notify the fitness of the resultant multicast trees of the GA 193 crossovers. The empirical study of the model evinced the discovery of optimal multicast tree with minimal energy 194 consumption and least end-to-end delay. The critical constraint of the proposal is computation overhead, since 195 the genetic algorithm process complexity is not linear, hence the process complexity is complimented if network 196 size is increased. The other constraint of the model is, it is not considering the overall multicast tree lifespan as 197 a factor route selection. 198

The review of contemporary multicast routing with minimal energy consumption and maximal network lifespan models was done here in this section. The review evincing that the all of these models are found to be fit under the specific factors considered. All of these models are divergent at multicast route discovery process in order to achieve minimal energy consumption and maximal network lifespan. The common constraints of these models observed is limiting the performance if transmission influenced by

²⁰⁴ 7 Global Journal of Computer Science and Technology

Volume XVI Issue IV Version I () noise, computational overhead observed in route discovery phase and process 205 overhead observed at route maintenance phase. This manuscript reviewed the energy efficient multicast routing 206 strategies found in recent literature. The review evinced the context of the multicast routing protocols and the 207 strategies followed in order to achieve energy efficient transmission and limits. The multicast routing models 208 reviewed were fall in either of the routing topologies called tree, mesh, zone and hybrid topology, but common 209 objective of all these protocols is multicast routing under minimal energy consumption and maximal network 210 lifespan. The review of these models reveal that scalability issues such as compatibility to dense networks, nodes 211 with high mobility and transmissions under noise in fluences are not considered by most of the approaches. The 212 assessment of the performance of all these models are at limited extent of QoS factors and heterogeneous factors 213 of mobile ad hoc networks such as all-to-all multicast routing, many-to-many multicast routing and multiple 214 unicast routing. Hence it is obvious to notify that a vast research scope to devise energy efficient multicast 215 routing protocols. $^{1\ 2}$ 216
