7 Abstract

Software testing is the process of running an application with the intent of finding software 8 bugs (errors or other defects). Software applications demand has pushed the quality assurance 9 of developed software towards new heights. It has been considered as the most critical stage of 10 the software development life cycle. Testing can analyze the software item to identify the 11 disparity between actual and prescribed conditions and to assess the characteristics of the 12 software. Software testing leads to minimizing errors and cut down software costs. For this 13 purpose, we discuss various software testing techniques and strategies. This paper aims to 14 study diverse as well as improved software testing techniques for better quality assurance 15 purposes. 16

17

Index terms— testing techniques, testing tools, verification, validation, level of testing, debugging, software testing objectives, software testing principles.

20 1 Introduction

oftware development involves developing software against a set of requirements. Software testing is needed to 21 verify and validate that the software that has been built to meet these specifications. Software testing helps in the 22 prevention of errors in a system. It refers to the process of evaluating the software to find out the error in it. It is 23 24 also used to analyze the software for other aspects of the software like usability, compatibility, reliability, integrity, 25 efficiency, security, capability, portability, maintainability, etc. Software testing aims at achieving specific goals and principles which are to be followed. In simple words, testing is the process of locating errors in the program. 26 Software Testing is executing the software to (i) perform verification, (ii) to detect the mistakes and (iii) to 27 achieve validation. 28 i. Verification: It is the process of checking the software concerning the specification. [Verification: Are we 29

i. Verification: It is the process of checking the software concerning the specification. [Verification: Are we making the product, right?] ii.

Error Detection: It is the process of deliberately performing the wrong inputs to check the system's performance. iii.

Validation: It is the process of checking software concerning the customer's expectation. [Validation: Are we 33 making the right product?] Testing is characterized as a process of assessment that either the definitive system 34 35 meets it's specified fulfillments initially or not. It is mainly a system beset with the validation and verification process that whether the developed system meets the fulfillments defined by the customers. Therefore, this 36 37 activity draws the difference between the actual and expected result. So, this is an analysis that provides the associates with the proper knowledge about the quality of the product. Software Testing can also be defined 38 as a risk-based activity. The testing cost and errors can be found in a relationship in figure 1. It is apparently 39 demonstrated that cost rises dramatically in a testing (functional and nonfunctional). The compelling testing 40 goal is to do the optimal amount of tests so that additional testing endeavor can be minimized. From Figure 1, 41 we can say that Software testing is an essential factor in software quality assertion. Bug: It means that when a 42 developer makes the error while coding. It is the state which is responsible for the failure of the specific function. 43

Fault: It is the representation of the error, where representation is the mean of expression that may be diagrams, flow charts, etc.

46 Failure: Failure occurs when a fault is executed.

⁴⁷ 2 b) Software Testing Objectives

48 The fundamental objective of software testing is to provide a quality product regarding the reliability estimation

and complete verification and validation of the product. The secondary aim of testing includes executing a
 program with the intent of finding errors and producing a test case which is capable of detecting the undiscovered
 error as yet.

52 **3** II.

53 4 Literature Review

In this section, we will outline the previous works of Software Testing. According to "The Theory of Software Testing", testing is the means of showing the presence of errors in the program which can either be performed manually or automatically. It also includes the basic terminology of testing such as automated testing, failure, testing team, and wrong test case selection. This paper focuses on the process that should be followed to test the performance of new software and the entire system. The conclusion of the article is the complete view of software testing, preliminary testing, and user acceptance testing.

60 **5** III.

61 6 Software Testing Methodologies

The importance of software testing to software quality cannot be overemphasized. After the development of the 62 code, it is mandatory to test the software to identify all the errors, and they must be debugged before the release 63 of the software. Although it is impossible to identify and debug all the errors in the significant software at every 64 phase, it is tried to remove all the mistakes as possible. Testing helps in finding the bugs; it cannot conclude that 65 the software is bug-free. We broadly categorized testing techniques into two parts: Internal specifications and 66 structures of the system are created conspicuous. So, it's acutely costeffective in detecting and resolving problems. 67 Bugs will be found before they cause bickering. Thus, we will summarize this approach as testing software with 68 the data of its internal structure and coding. White box testing is also familiar as precise box analysis or white 69 box analysis or glass box testing or transparent box testing, and structural testing. It's an approach for finding 70 errors within which the tester has complete data. This technique isn't used much for debugging in large systems 71 and networks. Different types of white box testing include basis path, loop testing, control structure testing, 72 etc. White-box testing tests internal constructions or workings of a program because programming skills and the 73 domestic context of the system are used to design test cases. The tester appoints inputs to apply paths through 74 the code and finalize the appropriate outputs. This is akin to testing nodes in a circuit. White-box Testing can 75 be used at the unit, integration and system levels of the software testing process. It usually is done at the unit 76 level. Although this approach of testing can expose many errors, it may not identify the missing requirements 77 and unimplemented parts of the specification. 78

⁷⁹ 7 White-box Testing includes the following approaches:

? Application Programming Interface testing tests the application using public and private APIs by creating tests 80 to satisfy some criteria for code coverage. ? Fault Injection Methods -Introducing faults to gauge the efficacy of 81 testing strategies intentionally. ? Code coverage tools can assess the integrity of a test suite that was created 82 with any method, including black-box testing. This grants the software team to check the parts of a system that 83 are rarely tested and assures that the most important function points have been verified. ? Function coverage is 84 the approach which informs on functions that have been executed. ? Statement coverage is the approach which 85 informs the number of lines executed to complete the test 100 per cent. It assures that all code paths or branches 86 are executed at least once. This helps to ensure correct functionality. 87

88 Advantages:

1. It exposes an error that is hidden in code by eliminating extra lines of code.
2. Maximum coverage is obtained
during test outline writing.
3. The developer discreetly gives reasons for implementation.

91 9 Disadvantages:

92 1. An experienced tester is required to carry out this procedure because knowledge of internal structure is needed.
93 2. Many paths will remain untested since it is challenging to look into every pros and con.

⁹⁴ 10 b) Black Box testing

95 A black box testing is a testing in which internal specifics and workings aren't known or accessible to its customer.

96 It supports specifications and output needs. The fundamental purpose is to identify the requirements of the

97 system. Black box testing has very little or no data on the inner logical structure of the system. Thus, it solely

se checks the basic features of the system. It assures that every input is appropriately accepted and outputs are

⁹⁹ correctly produced. **??**lack 3. Programmer and validators both are independent of each other.

100 11 Disadvantages:

101 1. Test cases are difficult to design without fair stipulations. 2. Probability of having the repetition of tests that 102 are already done by the programmer. 3. Here, some parts of the back end are not tested at all.

¹⁰³ 12 c) Grey-Box Testing

Gray box testing is the technique of testing the software with limited knowledge of the internal structure and design of the application. It is defined as a testing software package which has some data of its internal logic and underlying code. It uses internal information structures and algorithms. This approach holds necessary conducting integration testing between two or more modules of code written by totally different developers. This approach includes reverse engineering to work out on the boundary values. Grey box testing is unbiased and non-intrusive.

Grey-box Testing has the knowledge of internal data structures and algorithms for purposes of designing tests while executing those tests at the user level. The tester does not have full access to the software's source code. The following one come orbitmes of even how testing:

112 The following are some subtypes of grey-box testing:

113 **13 Disadvantages:**

114 1. Test coverage is limited because the access to source code is not available. 2. Many program paths remain 115 untested. 3. The test cases can be redundant.

116 14 Nonfunctional Testing Techniques:

It is a type of testing which is performed to test various attributes of a system like stress, load, etc. Nonfunctional 117 testing is performed at all test levels. It is concerned with the nonfunctional requirements and is explicitly modeled 118 to assess the readiness of a system according to the various criteria which are not covered by functional testing. 119 a) Performance Testing: It assesses the entire performance of the system. It is used to evaluate the system's 120 performance under a specific workload. b) Load testing: A load test is performed to ensure the load taking the 121 capacity of a particular order. Load testing is performed to determine the behavior of the system under normal as 122 well as peak load conditions. c) Endurance Testing. It is the type of testing performed to determine the system's 123 behavior after a particular time. For example, a method is working perfectly fine in the initial first hour, but the 124 performance decreased after three hours of execution. d) Stress Testing: It is performed to determine the system 125 performance beyond standard operational capacity, often to a breaking point. It is concerned with the system's 126 load taking ability. e) Security Testing: Security testing is done to assess that the system is safe or not. It is 127 a process that is concerned with the fact that an information system protects data and maintains functionality 128 as intended. f) Recovery Testing: Recovery testing is performed to check the recovery of the system after the 129 crash or hardware failure. In this type, the software is forced to fail under a given circumstance and then finally, 130 the recovery is tested. harmony of the developed system with the various other components such as hardware, 131 additional software, DBMS and operating system, etc. 132

133 IV.

¹³⁴ 15 Software Testing Strategies

Software Testing strategies provide a method of integrating software test case design methods into a well-planned Series of steps that can result in the successful construction of software. It provides the road map for testing. The software testing Strategy should be pliable enough to develop a customized testing approach. The software testing strategy is actually produced by project managers, software engineers, and testing specialists. There are four different types of software testing strategies: 1) Unit testing 2) Integration testing 3) Acceptance/Validation testing 4) System testing

141 **16** Unit testing

Unit is the smallest testable part, i.e. the most modest collection of lines of code which can be tested. Unit testing is done by the developer as the proper knowledge about the core programming designing is required. Generally, unit testing is considered as a white-box testing class because it is partian to evaluate the code as

¹⁴⁵ implemented rather than assessing conformance to some set of requirements.

Benefits of Unit Testing: 17146

1) Cost-effective testing technique. 147

2) Simple testing technique because the smallest testable unit of the code is tested here. 3) Individual parts are 148 tested when necessary, without waiting for another part of the system. 4) Unit testing can be performed in parallel 149 by fixing problems simultaneously by many engineers. 5) Detection and removal of defects are much costeffective 150 compared to other levels of testing. 6) Be able to take advantage of several formal testing approaches available 151 for unit testing. 7) Clarify debugging by limiting to a small unit the possible code areas in which to search for 152 bugs. 8) Be able to test internal logic that is not easily reached by external inputs in the broader integrated 153 systems. 9) Attain a high level of structural coverage of the code. 10) When debugging severe problems, it avoids 154 lengthy compile-build-debug cycles. 155

Acceptance testing 18 156

In this approach, testing is carried out to authenticate whether the product is developed as per the standards 157 and detailed criteria and meets all the requirements specified by the user. The user carries this Year 2 019 (158) type of testing where the product is developed externally by the third party. Acceptance testing falls under 159 the black-box testing approach, where the user is not very much involved in the internal working of the scheme. 160 Acceptance testing approach is also known as validation testing, QA testing, final testing, factory acceptance 161 testing and application testing, etc. In software engineering, acceptance testing may be executed at two different 162 levels; one at the system provider level and another at the end-user level. 163

Classification of Acceptance Testing: 19164

i. User Acceptance Testing: User acceptance testing is an essential step before the system is finally deployed to 165 the end-user. User acceptance testing is generally done by the actual software uses to ensure that it can handle 166 the specified task in the real world scenarios. ii. Alpha Testing & Beta Testing: QA teams or developers generally 167 have done this type of testing. Unit testing, Integration testing and System testing combine name as alpha testing. 168 Alpha testing is conducted in the presence developers and in the absence of users. In this testing, the following 169 criteria are examined such as spelling mistakes, broken lines, cloudy direction etc. After completing the alpha 170 testing successfully, beta testing is performed. Beta testing is conducted by real users who actually handle the 171 software in realworld scenarios. The customers provide their assessment to the developer for the outcome of the 172 experiment. It is also known as field testing. Feedback from the users is used to improve the performance of the 173 system/product before it is released to other users/customers. iii. Operational Acceptance Testing: Operational 174 acceptance testing (functional preparedness testing) is an approach of assuring all the specified processes and 175 procedures of the system are in place to allow user/tester to use it. iv. Contact and Regulation Acceptance 176 Testing: 177 The system is tested against the required criteria as mentioned in the contract document and also proved to 178

check if it meets all the government and local authority rules and regulations, even all the essential standards. 179

System testing 20180

System testing is a level of software or hardware testing where testing is conducted on a complete, integrated 181 system to assess the system's compliance with its specified requirements. System testing falls within the category 182 of black-box testing. The purpose of system testing is to evaluate the system compliance against the specified 183 requirements. Some of the Different types of system testing are as follows: 184

185 i. Recovery testing ii.

- Security testing iii. 186
- Graphical user interface testing iv. 187

Compatibility testing i. Recovery Testing: In this process of testing an application is able to recover from 188 crashes, hardware failures and other similar problems. If recovery is automatic, re-initialization, checkpointing 189 mechanisms, data recovery, and restart are evaluated for correctness. Recovery testing force the software to fail 190 in a variety of ways to assess that reconstruction is performed correctly. ii. Security testing: Security testing 191 tries to evaluate those protection mechanisms built into a system will protect it from erroneous penetration. 192 During security testing, the tester individually desires to penetrate the system. The validator may try to acquire 193 passwords through external clerical means; may attack the order with custom software designed to breakdown 194 195 any defenses that have been constructed; may overwhelm the system, thereby denying service to others; The goal of security testing is to identify the threats in the system and measure its potential vulnerabilities. iii. Graphical 196 197 user interface testing: In this testing approach, the product's graphical user interface is involved to ensure it 198 meets its written specifications. GUI testing attempts to check the screens with the controls like menus, buttons, icons, and all types of bars -toolbar, menu bar, dialogue boxes, and windows, etc. iv. Compatibility testing: 199 Compatibility testing is concerned with checking the system's compatibility with the rest of the environment. 200 It checks the harmony of the developed system with the various other components such as hardware, additional 201 software, DBMS and operating system, etc. 202 V.

203

204 21 Discussion

In this section, the difference between testing and debugging is shown. Software testing is a process of executing a program in order to identify whether it meets the specified requirement or not. The test case design is conducted, a strategy can be defined, and results can be evaluated against prescribed expectations. Debugging is the process of fixing the problems that are found during the software testing process. It is a consequence of successful testing. That is when testing uncovers a defect, debugging is the process that leads to the removal of the error. The debugging process can be done by the programmer or the developer. Based on the defect that is reported, the developers try to find the root causes of the error to

²¹² 22 Global Journal of Computer Science and Technology

Volume XIX Issue II Version I 48 Year 2 019 () C make the system defect free. Debugging is done in the three phases of software development. The first one is during the coding process when the programmer translates the design into executable code. In the coding process, the errors that are made by the programmer when writing in code needs to be detected quickly and fixed before going to the next phase of development. In these cases, the developer performs unit testing to identify any defects at the module or component level. Then debugging is performed during the last stage of testing. These involve debugging multiple components or a complete system, when unexpected behavior such as wrong return codes or abnormal program termination may be found.

220 **23** VI.

221 24 Conclusion

To conclude our survey, we would like to find that Software testing is an essential activity of the Software 222 Development Life Cycle (SDLC). We can never say that a product is "Perfect". Testing is a never-ending 223 process. Testing only shows the presence of errors, not the absence. It is time-consuming and an intensive 224 process, therefore, upgraded techniques and innovative methodologies are necessary to maintain the quality of 225 the software. This leads to performing Automated Testing implementation before and during the testing process. 226 This paper aims to describe in detail various software testing techniques, the need for software testing, software 227 testing goals, and objectives. Software testing is often less formal and meticulous than it should. In order to 228 perform software testing effectively and efficiently, those who are involved in testing must be familiar with the 229 basic concept, goals and principle of software testing. 230

We further discuss different software testing techniques such as white-box Testing, black-box Testing, greybox Testing, Security testing etc. Hence, the future work in relevance with the testing process will be much more technology-dependent harnessing the simulation and automated testing model-based approach, not only expediting the testing life cycle but also providing optimum bug prevention and efficient quality assurance.
