## Abstract

Digital image processing has been a significant and important part in the realm of computing science since its inception. It entails the methods and techniques that are used to manipulate a digital image using a digital computer. It is a type of signal processing in which the input and output maybe image or features/characteristics associated with that image. In this age of advanced technology, digital image processing has its uses manifold, some major fields being image restoration, medical field, computer vision, color processing, pattern recognition and video processing. Image inpainting is one such important domain of image processing. It is a form of image restoration and conservation. This paper presents a comparative study of the various digital inpainting algorithms provided by Open CV (a popular image processing library) and also identifies the most effective inpainting algorithm on the basis of Peak Signal to Noise Ratio (PSNR), Structural Similarity Index (SSIM) and runtime metrics.

## 1 Introduction

Image processing is the technique of performing operations on an image to enhance the quality of the image, extract useful information from it, or manipulate it for better usage. Digital image processing techniques are applied in fields of computer vision, pattern recognition, video processing, image restoration and image correction [1].

Image restoration [2] and correction entails all the techniques used to restore a damaged image. It includes noise removal from the image, correcting a blurred photo, enhancing an image with defocused subject, converting a black and white image to color image, removing stains and unwanted marks from the image, etc. Image inpainting is one such technique that falls under image restoration.

Image inpainting [3] is a form of image restoration and conservation. The technique is generally used to repair photos with missing areas due to damage or aging, or mask out unpleasant deformed areas of the image. The use of inpainting can be traced back to the 1700s when Pietro Edwards, director of the Restoration of the Public Pictures in Venice, Italy, applied his scientific methodology to restore and preserve historic artworks. The modern approach to inpainting was established in 1930 during the International Conference for the Study of Scientific Methods for the Examination and Preservation of Works of Art. Technological advancements led to new applications of inpainting. Since the mid-1990's, the method of inpainting has evolved to include digital media. Widespread use of digital inpainting techniques range from entirely automatic computerized inpainting to tools used to simulate the process manually. Digital inpainting includes the use of software that relies on sophisticated algorithms to replace lost or corrupted parts of the image data. There are various advanced inpainting methodologies [4], namely Partial Differential Equation (PDE) based inpainting [5], Texture synthesis based inpainting [6], Hybrid inpainting [7], Example based inpainting [8] and Deep generative model based inpainting [9].

In this paper, we have presented a detailed comparative study of the three inpainting algorithms natively provided by the Open CV library, and also stated which is the most effective algorithm out of them. The paper is structured as follows: Section II contains the related work done in the past on comparative analysis of inpainting techniques and algorithms. Section III contains a brief theory behind the inpainting algorithms to be discussed. Section IV contains the details of the comparative study and experimental setup. Section V presents the results we obtained from our study and their critical explanations. Section VI details the possibilities of further work

46 that can be performed on this topic. Section VII concludes the paper. We have focused more on the practical  
47 analysis of the three algorithms, and less on the theoretical and mathematical interpretation of the algorithms.

## 48 2 II.

## 49 3 Related Work

50 The first inpainting algorithm provided by OpenCV is established on the paper "An Image Inpainting Technique  
51 based on the Fast Marching method" by Alexandru Telea [10] in 2004. It is based on the Fast Marching  
52 Method. The second inpainting algorithm provided by OpenCV is established on the paper "Navier-Stokes,  
53 Fluid Dynamics, and Image and Video Inpainting" by M. Bertalmio et al [11] in 2001. It is based on fluid  
54 dynamics. The third inpainting algorithm was reviewed in the paper "Demonstration of Rapid Frequency Selective  
55 Reconstruction for Image Resolution Enhancement" by Nils Genser et al [12] in 2017. It is based on the Rapid  
56 Frequency Selective Reconstruction (FSR) method. They applied the algorithm on Kodak and Tecnick image  
57 datasets over custom error masks and presented the Peak Signal to Noise Ratio (PSNR), Structural Similarity  
58 Index (SSIM) and runtime metrics. We have used the same metrics for comparison, explained later in Section IV.  
59 Supriya Chhabra et al [13] presented a critical analysis of different digital inpainting algorithms for still images,  
60 and also a comparison of the computational cost of the algorithms. We have considered execution time and  
61 memory consumption as metrics to compare computational cost between the algorithms. Raluca Vreja et al [14]  
62 published a detailed analytical overview of five advanced inpainting algorithms and measurement benchmarks.  
63 They emphasized on the advantages and disadvantages of the used algorithms and also proposed an improved  
64 adaptation of the Oliviera's [15] and Hadhoud's [16] inpainting algorithms.

65 Kunti Patel et al [17] presented a study and analysis of image inpainting algorithms and concluded that  
66 exemplar based techniques are generally more effective than PDE based or texture synthesis based techniques.  
67 They also extensively listed the merits and demerits of the algorithms, which makes it easy to choose for end  
68 users without further research. Anupama Sanjay Awati et al [18] detailed a review of digital image inpainting  
69 algorithms, comparing hybrid techniques against commonly used ones. K. Singh et al [19] presented a comparison  
70 of patch based inpainting techniques and proposed an adaptive neighborhood selection method for efficient patch  
71 inpainting.

## 72 4 III.

## 73 5 Theory

74 OpenCV is a library of programming functions mainly aimed at real-time computer vision. It is a huge open  
75 source library for computer vision, machine learning, image and video processing tasks. OpenCV is used in a lot  
76 of machine learning problems like face recognition, object detection, image segmentation, etc. mainly due to its  
77 simple syntax and presence of a large number of predefined functions and modules.

78 There are several algorithms present for digital image inpainting, but OpenCV natively provides three of  
79 This algorithm is based on the paper "An Image Inpainting Technique based on the Fast Marching method" by  
80 Alexandru Telea [10] in 2004. It is based on the Fast Marching Method (FMM), a solutional paradigm which  
81 builds a solution outwards starting from the "known information" of a problem. It is a numerical method created  
82 by James Sethian for solving boundary value problems of the Eikonal equation [20]. A simple explanation of the  
83 working of the algorithm follows, extracted from the original paper [10].

84 The first and foremost step in any inpainting method is to identify the region to be inpainted. There is the  
85 region to be inpainted, also known as the unknown region and the surrounding known region of the image.

86 The algorithm first considers the boundary of the unknown region, which is of infinitesimal width, and inpaints  
87 one pixel lying on the boundary. Then it iterates over all the pixels lying on the boundary to inpaint the whole  
88 boundary. A single pixel is inpainted as a function of all other pixels lying in its known neighborhood by summing  
89 the estimates of all pixels, normalized by a weighting function. A weighting function is necessary as it ensures  
90 the inpainted pixel is influenced more by the pixels lying close to it and less by the pixels lying far away. After  
91 the boundary has been inpainted, the algorithm propagates forward towards the center of the unknown region.

92 To implement the propagation, the Fast Marching Method (FMM) is used. FMM ensures the pixels near the  
93 known pixels are inpainted first, so that it mimics a manual inpainting technique. The FMM's main advantage is  
94 that it explicitly maintains a narrow band that separates the known from the unknown image area and specifies  
95 which pixel to inpaint next.

## 96 6 b) INPAINT\_NS

97 This algorithm provided by OpenCV is established on the paper "Navier-Stokes, Fluid Dynamics, and Image  
98 and Video Inpainting" by M. Bertalmio et al [11] in 2001. This algorithm is based on fluid dynamics (fluid  
99 dynamics is a sub-discipline of fluid mechanics that describe the flow of fluids: liquids and gases) and utilizes  
100 partial differential equations. The method involves a direct solution of the Navier-Stokes equation [21] for an  
101 incompressible fluid. A simple explanation of the working of the algorithm follows, extracted from the original  
102 paper [11].

---

103 The basic principle is heuristic. After the user selects the unknown region, the algorithm first travels along  
104 the edges from known regions to unknown regions, and automatically transports information into the inpainting  
105 region. The algorithm makes use of isophotes (a line in a diagram connecting points where the intensity of light  
106 or brightness is the same). The fill-in is done in such a way that the isophote lines arriving at the unknown  
107 region's boundary are completed inside, which allows the smooth continuation of information towards the center  
108 of the unknown region. M. Bertalmio et al [11] drew an analogy between the image intensity function of an  
109 image and the stream function in a 2D incompressible fluid, and used techniques from the computational fluid  
110 dynamics to produce an approximate solution to image inpainting problem.

## 111 7 c) INPAINT\_FSR

112 FSR stands for Rapid Frequency Selective Reconstruction [12]. It is a high quality signal extrapolation algorithm.  
113 FSR has proven to be very efficient in the domain of inpainting. The FSR is a powerful approach to reconstruct  
114 and inpaint missing areas of an image.

115 The signal of a distorted block is extrapolated using known samples and already reconstructed pixels as  
116 support. This algorithm iteratively generates a generic complex valued model of the signal, which approximates  
117 the undistorted samples in the extrapolation area of a particular size as a weighted linear combination of Fourier  
118 basic function. The Fourier basic function is a method to smooth out data varying over a continuum (here the  
119 unknown region) and exhibiting a cyclical trend. An important feature of FSR algorithm is that the calculations  
120 are carried out in the Fourier domain, which leads to fast implementation.

121 There are two implementations of the FSR inpainting algorithm -INPAINT\_FSR\_FAST and IN-  
122 PAINT\_FSR\_BEST. The Fast implementation of FSR provides a great balance between speed and accuracy,  
123 and the Best implementation mainly focuses on the accuracy, with speed being slower compared to Fast.

124 IV.

## 125 8 Comparative Study a) Theoretical Comparison

126 All the three inpainting algorithms provided by OpenCV are unique and works on different methodologies. The  
127 similarity between the algorithms is the inpainting procedure starts with the pixels lying in the boundary of the  
128 unknown region, and slowly propagates towards the centre of the unknown region. All the three algorithms are  
129 heuristic in nature. The propagation method used in each is different. TELEA uses the Fast Marching Method  
130 (FMM), NS uses fluid dynamics equations and FSR extrapolates the pixel values of the unknown region using  
131 known samples.

## 132 9 b) Practical Comparison

133 For practical comparison of the 3 algorithms, we ran some code in Python. Our testing setup had the following  
134 specifications:

135 -CPU : i7-8700K (3.70 GHz) -RAM : 16 GB (3200 MHz) -GPU : 8 GB GTX 1080

136 We took the Kodak image set (which contains 25 uncompressed PNG true colour images of size 768x512 pixels)  
137 and four custom error masks for the dataset. We applied all the inpainting algorithms individually over each  
138 error mask on the images. We compared the results using four main metrics:

139 -Peak Signal to Noise Ratio (PSNR): It is the ratio between the maximum possible power of a signal and the  
140 power of corrupting noise. To estimate the PSNR of an image, it is necessary to compare the distorted image to  
141 an ideal clean image with the maximum possible power. PSNR is commonly used to estimate the efficiency of  
142 compressors, filters etc. A higher value of PSNR suggests an efficient manipulation method. In our case, we will  
143 compute the PSNR between the original image and the inpainted image. The Python code to calculate PSNR  
144 is given in Fig 2. -Memory: It is the total memory consumed by the algorithm while completing the task. We  
145 use tracemalloc module, which is a debug tool to trace memory blocks allocated by Python. We find the peak  
146 memory usage during the working of the algorithm.

## 147 10 Fig. 5: Memory code

148 All the values have been taken up to three decimal places. Apart from the four main metrics, we also considered  
149 two hybrid metrics defined in Section V. We also curated some custom images for testing of certain specific cases.  
150 The results obtained are given in the next section, along with their critical explanation.

151 V.

## 152 11 Results and Discussion

### 153 12 a) Kodak image dataset results

154 There are 19 landscape and 6 portrait oriented photos in the Kodak image set. We initially made the custom  
155 error masks for landscape orientation, and rotated them to fit the portrait orientation. We chose striped masks  
156 as the error regions are equally distributed. The four custom error masks we considered are: Fig. ???: Four  
157 custom error masks

158 The white stripes are the areas to be inpainted. We have displayed the image results for just 1 landscape photo  
 159 (2 error masks) and 1 portrait photo (2 error masks). These are the following results we obtained:-Sample\_1  
 160 (Landscape)

161 The original, distorted and 4 inpainted results of the first image sample over the first error mask are given in  
 162 Fig 7. The metric values calculated for the first image sample over the first error mask are given in Table 1. The  
 163 metric values calculated for the first image sample over the second error mask are given in Table 2. We have not  
 164 given the image results for the third and fourth error masks, only the metric values. The metric values calculated  
 165 for the first image sample over the third error mask are given in Table 3. The metric values calculated for the  
 166 first image sample over the fourth error mask are given in Table 4.

### 167 13 Sample\_2 (Portrait)

168 For portrait images, the error masks have been rotated 90 degree clockwise to fit the orientation. Given are the  
 169 original, distorted and 4 in painted results of the second image sample over the first error mask in Fig 9. The  
 170 metric values calculated for the second image sample over the first error mask are given in Table 5. The metric  
 171 values calculated for the second image sample over the first error mask are given in Table 6. We have not given  
 172 the image results for the third and fourth error masks, only the metric values. The metric values calculated  
 173 for the second image sample over the third error mask are given in Table 7. The metric values calculated for  
 174 the second image sample over the fourth error mask are given in Table 8. Generally speaking, lower memory  
 175 consumption and runtime values mean a better algorithm. For other metrics, the higher the PSNR and SSIM  
 176 value, the better the algorithm. The average memory consumption, as seen from Table 9,10,11,12 is same for  
 177 any mask on any image for any algorithm for the particular dataset. Hence we will not consider it as a factor for  
 178 deciding the most efficient algorithm. We have defined two hybrid metrics X and Y for deciding which algorithm  
 179 is most efficient based on our data. Metric X is directly proportional to PSNR, directly proportional to SSIM  
 180 and inversely proportional to Runtime value:  $X \propto \text{PSNR} \times \text{SSIM} \times (1/\text{Runtime})$

181 Combining all three above equations we get:  $X \propto (\text{PSNR} * \text{SSIM})/\text{Runtime}$   $X = k * ((\text{PSNR} * \text{SSIM})/\text{Runtime})$   
 182 where k is a constant, taken to be 1 for comparison purposes. Hence  $X = (\text{PSNR} * \text{SSIM})/\text{Runtime}$  A high  
 183 value of metric X means an effective algorithm. We used the values obtained in Table 9,10,11,12 and calculated  
 184 metric X values for the four error masks. The values are given in Table 13. From Table 13, we can see that  
 185 TELEA algorithm gets the highest value in all four error masks. Hence, TELEA is the most efficient in painting  
 186 algorithm when we consider metric X to be the comparison metric.

187 But as we can infer from the definition of metric X, it has the runtime factor associated with it. Runtime  
 188 is an important factor for analysing algorithms, but can be subjective at times to different end users. Some  
 189 users may have a time constraint, some users may not. Hence we need to define such a metric which does not  
 190 include the runtime factor. Therefore, we define metric Y. Metric Y is directly proportional to PSNR and directly  
 191 proportional to SSIM value:  $Y \propto \text{PSNR} \times \text{SSIM}$  Combining all two above equations we get:  $Y \propto \text{PSNR} * \text{SSIM}$   
 192  $Y = k * (\text{PSNR} * \text{SSIM})$

193 where k is a constant, taken to be 1 for comparison purposes. Hence  $Y = \text{PSNR} * \text{SSIM}$  A high value of  
 194 metric Y means an effective algorithm, without taking the runtime factor into account. Similarly, we used the  
 195 values in Table 9,10,11,12 and calculated metric Y values for the four error masks. The values are given in Table  
 196 14. From Table 14, we can see that FSR\_BEST algorithm gets the highest value in all four error masks. Hence,  
 197 FSR\_BEST is the most efficient inpainting algorithm when we consider metric Y to be the comparison metric,  
 198 which does not take the runtime factor into account.

199 Summing up our observation and results for the Kodak image dataset, we can say that the most efficient  
 200 inpainting algorithm when runtime is a constraint is TELEA algorithm and the most efficient inpainting algorithm  
 201 when runtime is not a constraint is FSR\_BEST algorithm.

### 202 14 b) Edge inpainting results

203 The inpainting algorithms produce very different results when working on edges. To compare the working, we  
 204 have chosen an image which has clear distinct foreground and background. We distorted a part of the edge, and  
 205 applied the inpainting algorithms to it. The image results are given in Fig 11, and metric values are given in  
 206 Table 15.

207 As we can see from the results, TELEA has the highest value for X metric. That is if we consider runtime to  
 208 be a factor, TELEA is the most efficient algorithm. But FSR\_BEST has the highest value for Y metric, i.e. if  
 209 we do not consider runtime to be a factor, then FSR\_BEST is the most efficient algorithm for edge inpainting.  
 210 We can also see from the image results that FSR\_BEST produces the most believable result, but also has the  
 211 largest runtime. TELEA and NS do a decent job in filling up the edges and maintaining the edge difference. But  
 212 still some parts are hazed and distorted. FSR\_FAST does the worst job, mainly because it trades off accuracy  
 213 for runtime, and the result is bad.

### 214 15 c) Pattern inpainting results

215 The inpainting algorithms produce very different results when working on patterns. To compare the working, we  
 216 have chosen a checkerboard image as it is the easiest pattern to replicate. We distorted a part of the image in

---

217 the centre, and applied the inpainting algorithms to it. The image results are given in Fig 12, and metric values  
218 are given in Table 16.

219 As we can see from the image results, none of the inpainting algorithms can replicate the pattern in the  
220 unknown region, which is understandable because the inpainting algorithms are focused on filling up the unknown  
221 region progressively based on information from the nearest known region. They work on the small scale spatial  
222 influences. In order to inpaint a pattern, the algorithm must work over a broad range of the known region to  
223 understand the dynamics of the pattern. An exemplar based inpainting or patch based inpainting method can  
224 work for pattern inpainting.

225 Comparing the metric values, TELEA has the highest X value and FSR\_BEST has the highest Y value. From  
226 the image results, TELEA still does a decent job of producing an arbitrary pattern, while FSR\_BEST fills the  
227 whole unknown region with a singular colour. Hence, no algorithm provided by OpenCV is perfectly suitable for  
228 inpainting a pattern, but TELEA can be used as a last resort.

## 229 16 d) Text error mask inpainting results

230 We also tested the working of the inpainting algorithms on a custom text error mask. We took an image from  
231 the Kodak dataset and wrote some random text on it as error regions, then applied the algorithms on it. The  
232 image results are given in Fig 13, and metric values are given in Table 17.

233 Comparing the metric values, NS has the highest X value and FSR\_BEST has the highest Y value. All  
234 the algorithms work decent, but from the image results we can see that TELEA and NS have some distortions  
235 near the fence area, while FSR\_FAST and FSR\_BEST have inpainted smoothly in that area. If runtime is a  
236 constraint, then NS is the most effective algorithm to be used. Although, TELEA can also be used as it produces  
237 very similar results to NS. If runtime is not a constraint, then FSR\_BEST is the most effective choice for text  
238 error mask inpainting.

## 239 17 e) Monochromatic image inpainting results

240 We tested the working of the inpainting algorithms on a monochromatic image. We took an image from the  
241 Kodak dataset and converted it into monochrome and used a spiral error mask on it. The image results are given  
242 in Fig 14, and metric values are given in Table 18.

243 Comparing the metric values, NS has the highest X value and FSR\_BEST has the highest Y value. All the  
244 algorithms work decent, but from the image results, we see that TELEA and NS have some distortions near  
245 the beak of the bird, while FSR\_FAST and FSR\_BEST have inpainted smoothly in that area. If runtime is  
246 a constraint, then NS is the most effective algorithm to be used. Although, TELEA can also be used as it  
247 produces very similar results to NS. If runtime is not a constraint, then FSR\_BEST is the most effective choice  
248 for monochromatic image inpainting.

## 249 18 f) Discussions

250 Summing up our observations and results for the Kodak image dataset and other specific cases, we can say that  
251 the TELEA inpainting algorithm is the most efficient algorithm if runtime is a constraint i.e. the user needs to  
252 perform the inpainting operation as fast as he can and produce the best results. On the other hand, FSR\_BEST  
253 inpainting algorithm is the most efficient algorithm if runtime is not a constraint i.e. the user has no time limit  
254 for the inpainting operation and wants to get the best result. The average memory consumption for all the  
255 inpainting algorithms are modest, hence memory will hardly be an issue in any system while running the Open  
256 CV inpainting algorithms.

## 257 19 Future Scope

258 Our inpainting comparison study was done on the Kodak image dataset, a relatively small dataset containing 25  
259 images only. The study can be done on a larger, more robust dataset which contains variety of images. This can  
260 be done to get more extensive results. We compared our results on the basis of four metrics only; more intricate  
261 metrics may be defined for the testing. Our study can be a base for analysing how various OpenCV inpainting  
262 methods work on images with different colour profiles.

263 We ran tests using four custom error masks. The error masks considered were mostly linear in shape. Other  
264 type of error masks such as curved, mixture of linear and curved can be taken for testing. This study can be a  
265 base for a comprehensive study on video inpainting techniques, which would be beneficial for people looking to  
266 work in this field.

## 267 20 VII.

## 268 21 Conclusion

269 In conclusion, we present a comparative study of the various OpenCV inpainting algorithms, focusing extensively  
270 on their practical uses. The purpose of this paper is to apprise new users and researchers of the most efficient  
271 inpainting algorithm provided by OpenCV: TELEA algorithm for time constrained operations and FSR\_BEST

## 21 CONCLUSION

---

272 algorithm for non time constrained operations. We present the most efficient OpenCV inpainting algorithm to  
273 be used for various scenarios, which can help a beginner at inpainting to make his decision wisely without any  
274 further research. This study can be a base for more detailed comparative works on image and video inpainting.  
275 Inpainting is an evolving domain of image processing with major strides being made in the past, and much more  
276 sophisticated algorithms yet to arrive. It opens up the doorway for new image processing researchers to better  
the existing algorithms and create finer advanced inpainting algorithms which achieve near perfect accuracy.
