# Distributed Bioinformatics Computing System for DNA 1 Sequence Analysis 2 Chotan Sheel<sup>1</sup>, Dr. Mohammad Ibrahim Khan<sup>2</sup> and Dr. Kaushik Deb<sup>3</sup> 3 1 Received: 12 December 2013 Accepted: 1 January 2014 Published: 15 January 2014 5

#### Abstract 7

This paper provides an effective design of computing technique of a distributed bioinformatics 8 computing system for analysis of DNA sequences using OPTSDNA algorithm. This system 9 could be used for disease detection, criminal forensic analysis, gene prediction, genetic system 10 and protein analysis. Different types of distributed algorithms for the search and identification 11 for DNA segments and repeat pattern in a given DNA sequence are developed. The search 12 algorithm was developed to compute the number of DNA sequence which contains the same 13 consecutive types of DNA segments. A distributed subsequence identifications algorithm was 14 designed and implemented to detect the segment containing DNA sequences. Sequential and 15 distributed implementation of these algorithms was executed with different length of search 16 segments patterns and genetic sequences. OPTSDNA algorithm is used for storing various 17 sizes of DNA sequence into database. DNA sequences of different lengths were tested by using 18 this algorithm. These input DNA sequences varied in size from very small to very large. The 19 performance of search technique distributed system is compared with sequential approach. 20

Index terms— distributed bioinformatics system, DNA sequence, search segments, identify DNA sequences, 22 reported gene sequences. 23

#### 1 Introduction 24

istributed Computing (DC) provides a cost effective frame work with efficient execution of a solution on multiple 25 computers connected by a network. For distributed Computing (DC), large tasks are divided into smaller problems 26 which can then be executed on multiple computers at the same time independent of each other. The task must 27 be broken up into independent problems to minimize inter-computers communication; otherwise distributed 28 computing will not be effective. Over the past few years, the intermixing of computer science and the complexity 29 of biology has lead to the prosperous field of bioinformatics [1] ???] Advances in molecular biology and technology 30 for large portions of genomes in various species. Today computers have made medical research more efficient and 31 accurate, by using parallel and distributed computers and complex biological modeling. Bioinformatics, is one of 32 the newer areas, and has opened our eyes to a whole new world of biology [1]. 33 The fusion of computers and biology has helped scientists learn more about species, especially humans [3] 34

35 ??4][5]. With the aid of the computers, we have learned a great deal about genetics, but there still stand many 36 unanswered questions, that are being researched today. DNA sequence analysis can be a lengthy process ranging 37 from several hours to many days. This paper builds a distributed system that provides the solution for many 38 bioinformatics related applications.

The overall goal of this paper is to build a Distributed Bioinformatics Computing System for genetic sequence 39 analysis of DNA. This system is capable of searching and identifying gene patterns in a given DNA sequence. For 40 the purpose of computing we stored a large no. of DNA sequence using OPTSDNA algorithm [13] and segments is 41 divided two to six consecutive nucleotide [13]. The system was tested for its correctness and efficiency. Different 42

lengths of DNA sequences were used for the consecutive and nonconsecutive pattern search to compare the 43

system's response time obtained using single and multiple computers ??6]. In addition, different lengths of DNA
sequences were also used for the pattern identification to compare its response time observed using a single
computer and multiple computers. Several different distributed implementations of search algorithms have been

47 reported in the literature. The characteristics of some of those distributed algorithms are listed in Table 1.

48 It can be observed that the most of the existing approaches require high performance parallel processors 49 and are not implemented on loosely coupled distributed network. Moreover, most of them require specialized 50 programming language for their implementation on these parallel processors.

The specific objective of the proposed distributed algorithm for analysis of DNA sequences are: 1. Develop an effective distributed DNA sequence analysis algorithms for pattern matching of DNA Gene sequence and sub-sequences identification. 2. Implement them on loosely coupled distributed network such as regular local area network and , Bangladesh.

research have facilitated the process of sequencing of wide area network using standard programming language. 55 This paper is organized in four sections. Section 2 discusses the material and method of algorithm. Section 3 56 discusses the results and discussion and conclusions included in section 4. Bioinformatics system developed in 57 this paper could be used for disease detection, criminal forensics analysis, genetics systems and protein analysis. 58 59 Di-let, Triplet, Tetra-let, Pentad-let, Hexed-let repeats formally known as a Di-nucleotide, Trinucleotide, Tetra-60 nucleotide, Pent nucleotide, Hex nucleotide. Repeat occurs when two, three, four, five and six consecutive 61 nucleotides are repeated within a specific region of DNA sequence. These repeats can occur within or between 62 genes. These consecutive repeats are frequently located in genes that encode transcription factors and which are active in the organism development process. Extensive Di-let, Triplet, Tetra-let, Pant-lets, Hex-let repeats 63 are found when a mutation occurs in a gene. This mutation increases the number of occurrences of a particular 64 nucleotide which can lead to a number of neurodegenerative diseases. These diseases include, Huntington's Disease 65 (HD), Fragile X Syndrome, Kennedy's Disease, Myotonic Dystrophy, Spinocerebellar Ataxia Type 1 (SCA1), 66 Dentatorubral Pallidoluysian atrophy (DRPLA), and Fragile X E mental retardation (FRAXE). In Kennedy's 67 Disease, Huntington's disease, Spinocerebellar Ataxia Type 1, and Dentatorubral Pallidoluysian atrophy, the 68 number of triplet repeats is quite small, in contrast to Fragile X Syndrome, Myotonic Dystrophy, and FRAXE, 69 where the number of consecutive repeats may be very large, producing alleles that consist of thousands of repeats. 70 These algorithms can help to detect Di-let, Triplet, Tetra-let, Patna-led and Hex-let repeats in gene sequence, and 71 can also search through DNA sequences to identify most frequently occurring repeats. The proposed distributed 72 73 algorithms will be able to first identify a DNA sequence Gene pattern in the DNA obtained from the crime scene 74 and then it can search for those patterns in suspects DNA, which will be helpful for criminal investigation, Disease analysis, Gene Sequence Prediction, Human Identification etc. Criminal investigation can now be facilitated by 75 the DNA forensic analysis. Forensic analysis is a process by which two organism's DNA is compared with each 76 other. DNA analysis is effective in finding criminals, because two different individuals will have different DNA 77 sequence. In DNA analysis one can look for matching gene patterns at different locations of the suspect's DNA 78 and the DNA obtained at the crime scene. Gene pattern matching at one, two or three locations in DNA usually 79 aren't enough to associate a suspect with a crime, but gene pattern matches at 5 or more locations in DNA 80 are usually good enough to identify a criminal. Experts believe that DNA forensic technology is more reliable 81 than eyewitnesses, where the odds are fifty-fifty. In DNA analysis one can look for matches based on number of 82 repeating patterns at different locations of the suspect's genome. 83

#### **3** Materials and Method

The proposed distributed algorithm is based on client server model. For distributed search and identification 86 algorithms on DNA sequence, the proposed framework avoids duplicates computations on server machines. The 87 two input items are provided by the user for pattern search and identification: 1. The DNA sequence which 88 is stored by OPTSDNA algorithm with extend two to six consecutive nucleotides division. 2. Search string 89 DNA subsequences or identification DNA segments (Di-nucleotides to Hex-Nucleotides Segment pattern). Using 90 OPTSDNA algorithm, the DNA sequence is broken up in X segments where  $X = m^* p$ . Here m = number91 of storage DNA and p = length of storage nucleotide base. Number of storage DNA is also used as number of 92 servers used in distributed algorithm implementation and length of storage nucleotide base represents the length 93 of pattern for search or identification. In the first step each server gets one segment of data and the required 94 95 search or identification pattern for carrying out its computation as shown in Figure 1. In addition, an offset value 96 is sent to the server as well to make sure that no two servers are performing the same computation for search 97 or identification. The individual results from each server are sent back to the clients where partial results are 98 combined as shown in Figure ??. The complete details of client and server side interaction are shown in Figure 3. The actual pattern search for a DNA sequence with three servers is shown in Figure ??, where each server 99 starts the match at different Gene chromosome. 100

Different starting point at various servers guarantees that no comparison for pattern search and identification is performed more than once on any server. The worst case complexity of this distributed search or identification algorithm is O (L/X), where L is the length of DNA sequence and X = m/p. In case of Figure ?? value of X = 104 1 because m = 3 and p = 3. That implies that complete DNA sequence is end to all three servers and the offset 105 for starting the search or identification.

# <sup>106</sup> 4 a) Implementation of Distributed Algorithms

A Dot net based client server system was developed for this project [7][8] shown in figure ?? and figure B. The 107 client and server side logic implementation is given in Figure 3 and figure 4. This framework can distribute the 108 workload across multiple servers as specified by the user. In this paper, a client provides the user input from 109 Graphical User Interface (GUI) and then send this input to one or more server computers as directed by the user 110 (shown figure ?? and B). The processing option is developed in GUI. When a client selects a processing option 111 such as pattern identification, appropriate input for carrying out a search or identification in a DNA sequence 112 displayed (shown in figure ?? and B). The client program then sends the input data to multiple servers (as 113 specified by the user). The code at the server executes the desired algorithm and returns its results to the client. 114 The client then receives the results from all the servers and combines to individual results to generate a final 115 output of the processing a shown in figure ?? and figure B. 116

## 117 5 Results and Discussion

Sequential and Distributed versions of the algorithms were executed with different patterns of genetic sequences. 118 These sequences were of different sizes ranging from very small to very large. The response times for sequential 119 and distributed versions of the programs were plotted to demonstrate the effectiveness of distributed DNA 120 sequence analysis algorithms. of consecutive pattern search execution on single machine and multiple machines. 121 The execution time was calculated for DNA sequences of sizes 1 to 1000 sequences. It can be observed that 122 execution time reduces significantly as number of servers increased. Moreover, the improvement in execution 123 time is significant when DNA sequence size is 600 with 3 servers. Figure ??, 6 and 7 shows the response time of 124 125 consecutive pattern identification execution on single machine and multiple machines. It can be observed that the execution time reduces significantly as number of servers increased. 126

Similar observation was made for sequential approach consecutive pattern identification algorithm execution shown in Figure ??, 6, and 7. Figure 8 demonstrates how the data size affected the computation time. With a single computer the response time of each gene sequence was significantly more than that of the distributed execution using two and three servers. In addition, rate of growth of execution time is almost linear with three servers as the size of DNA sequence increases.

### 132 **6** IV.

## **133** 7 Conclusions

As shown in the previous figures, it is clear that as complexity of the algorithm increases the response time 134 also increases. The algorithm for the Pattern Identification was the most complex one and the algorithm for the 135 pattern search was the least complex. It can be seen in Figure ?? the response times for the Pattern Identification 136 were much lower compared to the other two studies shown in Figures ?? and 6. This is due to the fact that 137 more complex algorithms usually involve more steps, which increases the response time. To help get a better 138 understanding of the effects of Distributed Systems on DNA sequences, more DNA sequences of various lengths 139 should be tested. This would provide more data for a larger analysis. It is also recommended that the computers 140 used in the investigation should not exceed the length of the repeat pattern that is being searched or identified, 141 because this will not improve the response time. The complexity of our algorithm is O(n). For computing DNA 142 sequences special purpose of computer is required. Using this algorithm no. of computer required is flexible and 143 special language is required. Our algorithm is useful on general network. So our algorithm is more efficient then 144 previous all. In addition, this system could be interfaced with the Internet, so that all these feature of DNA 145 analysis are accessible to everyone via Web. 146
