Bayesian Regularization Based Neural Network Tool for Software Effort Estimation Harwinder kaur¹ and Dalwinder Singh Salaria² ¹ Lovely Professional University Received: 14 April 2013 Accepted: 5 May 2013 Published: 15 May 2013

7 Abstract

Rapid growth of software industry leads to need of new technologies. Software effort 8 estimation is one of the areas that need more concentration. Exact estimation is always a 9 challenging task. Effort Estimation techniques are broadly classified into algorithmic and 10 non-algorithmic techniques. An algorithmic model provides a mathematical equation for 11 estimation which is based upon the analysis of data gathered from previously developed 12 projects and Non-algorithmic techniques are based on new approaches, such as Soft Computing 13 Techniques. Effective handling of cost is a basic need for any Software Organization. The 14 main tasks for Software development estimation are determining the effort, cost and schedule 15 of developing the project under consideration. Underestimation of project done knowingly just 16 to win contract results into loses and also the poor quality project. So, accurate cost 17 estimation leads to effective control of time and budget during software development. This 18 paper presents the performance analysis of different training algorithms of neural network in 19 effort estimation. For sake of ease, we have developed a tool in MATLAB and at last proved 20 that Bayesian Regularization [20] gives more accurate results than other training algorithms. 21

27 1 I. Introduction

oftware effort estimate is one of the noticeable & mind catching field. But since it was started, it is challenging 28 factor for software industry and Academia to realize the exact estimation of software development. In today's 29 fast changing world, success in managing projects is a critical factor for the success of the entire organization. 30 Estimation that either overestimated or underestimated both is very critical. In case of Overestimating time 31 and effort (or budget), due to a presumed lack of resources or because the projected completion is too late, can 32 33 convince management not to approve projects that may otherwise contribute to the organization. On the other 34 hand, underestimation may result in approval of projects that will fail to deliver the expected product within 35 the time and budget available. There are many factors that influence the Software estimation, some of them are: uncertainty, level of detail of preparing the project plan, managerial factors, lack of past data, pressure to lower 36 estimation and estimator experience [1]. In spite of the critical role of accuracy, examples of incorrect estimation 37 abound, especially in IT projects, resulting in enormous waste of time and money. Some techniques which were 38

used in the past are not in use during present time, like SLIM [14], checkpoint [2], Seer [2]. In all the way of work time, many of new advance roads have been suggested for effort estimation like Genetic programming [11],

41 Fuzzy logic [10], Neural Network [15], data mining [9], etc.

4 III. INTRODUCTION TO NEURAL NETWORK AND TRAINING ALGORITHMS

One cannot state that one model give better accuracy above all. Each and every give different level of accuracy in different Environment. But in recent days, Neural Network gains main attention due to many flavor of algorithm available for it. The main focus of this paper is to investigate the accuracy of estimation using neural network approach based on three different training algorithms: Levenberg-Marquardt (trainlm) [20], Back propagation [20], Bayesian Regularization (trainbr) ??20] and this has been done with the help of tool generated by us in MATLAB.

This paper comprises as follow: section II describes the some former effort estimation models and review of related work to Neural Network, section III includes introduction of Neural Network and training algorithms used for this paper, in section IV problem is stated, section V describes methodology used, section VI includes experimental results and comparisons. In last conclusion and future scope is given.

52 **2** II.

⁵³ **3** Review of Literature

The period of Effort Estimation was started from the expert judgments, which is based on the experiences of experts. But it is only proceed as pillar when current project & pertinent Past projects are similar. Choices of effort estimation techniques footstep from COCOMO [14] to AI approaches [2]. In 1970, Larry Putnam developed the method SLIM [14], based on the Rayleigh function and the influence used to Rayleigh curve was Manpower Buildup Index (MBI and Productivity Factor (PF) [2]. Linear programming was key work to drive effort estimation in SLIM [14] and depend upon the source line of code.

In of an easy going & understandable model, could call the effort & time period of project. Due to some problems and some misses found in COCOMO, later on Barry Bohem developed the advance road of this model i.e. COCOMO 2.0 [7]. As growth of software industry rising tremendously and previous version was not up to need.

After that, Howard Rubin proposed the ESTIMAC model to estimate effort at conception stage [4]. Equations 64 used in this model are not available, because it was a proprietary model. ESTIMAC is high level model but 65 doesn't provide accurate solution [3]. Six critical estimation dimensions identified by Rubin for this model 66 67 are: effort hour, staff size, cost, hardware resource requirement, risk, portfolio impact [2]. But these methods (COCOMO, SLIM, ESTIMAC) are based on Line of code (LOC). The main problems in Line of Code methods 68 are: lack of universally accepted definition for exactly what line code really is? Other side line of code is language 69 dependence. So, in 1979 IBM, developer Allan Albrecht developed measurement method called Function point 70 [3] in order to reduce the issues related with LOC methods. Function point defines the complexity of software 71 system in terms of functions that system delivers to user. It comprise linear combination of five basic software 72 components (input, output, master files, interfaces, inquiries) consider to be low, average, high [3]. In 1990, GC 73 Low and DR. Jeffery also concluded in their paper that Function point method is more consistent then the line of 74 code measure [6]. But on the other side, function point method is unable to deal with Uncertain, imprecise and 75 incomplete data. Many researcher's use different Neural Network with different datasets in order to generate more 76 accurate result for effort estimation. The main advantage of neural network is its ability to handle non-linear 77 data and confidence in decision making. In 1995, Krishna moorthy Srinivasan and Douglas Fisher applied the 78 machine learning approach for Software Effort Estimation [16]. They applied the Back propagation algorithm 79 80 on COCOMO dataset, along with configuration of 33 neuron of input layer, 10 neurons for hidden layer and 1 output neuron. Actually they had done three experiments on different datasets. They concluded that Back 81

⁸² propagation competitive again traditional approaches but quite sensitive.

In one paper written by Ali Idri, et al. [17] in 2002, in which he uses COCOMO-81 dataset and three layered back-propagation ANN, concluded that accuracy provide by back propagation is acceptable.

In 2005, N Tadayon compares the three models COCOMO II, Neural Network and expert judgments to state the strength of different estimation techniques [13]. In 2006, according to Barcelos Tronto et.al Neural Network approach provides better tune result than the linear regression [18]. In his methodology, he used the Back propagation as training algorithm on COCOMO dataset.

In 2010, Iman Attarzadeh, proposed new model of COCOMO II using neural network, and comcluded that neural network approach gives best accuracy than COCOMO II.

Mrinal Kantri, et al. [19] implemented a backpropagation ANN of 3-3-1 architecture on Lopez Martin dataset consist of 41 projects. There are many other techniques such as ordinary least square (OLS) [2], Case based reasoning [12], Date mining [9], Bayesian COCOMO II [2], Genetic Programming [5] etc. also used for the effort estimation but not discussed in this paper.

⁹⁵ 4 III. Introduction to Neural Network and Training Algorithms

A Neural Network is massively distributed processor made up of simple processing elements called neuron, which model some functionality like human brain [15]. The use of Neural Network offers the some useful properties and capabilities: -Nonlinearity, Adaptivity, Evidential Response, Confidence in decision made. A primary advantage of learning systems is that they are nonparametric; predictive models can be tailored to, the data at a particular site [8]. One of the problems that occur during above neural network training algorithms is over fitting. Due to this, error in early stage is very small, but, when new data is presented to the network the error is large. The solution to this problem is Bayesian regularization (trainbr) ??20]. trainbr updates the weight and bias values
according to Levenberg-Marquardt [20] optimization. It minimizes a grouping of squared errors and weights,
and generates a network that generalizes well. The process is called Bayesian regularization. It is suitable
method for estimation when large number of inputs is used for best output. Till now, Levenberg-Marquardt and
Back-propagation algorithm used by many researchers for training phase.

¹⁰⁷ 5 IV. Problem Statement

The main aim of any software development organizations is to finish the project within acceptable or customary 108 schedule and budget. Budget is mainly driven by labor cost and time and together they form a measure called 109 effort. From quality point of view estimating effort is one of the major important factors. Because estimation 110 either it be over estimate or under estimate, produces worst results. In case of over estimation of time and effort 111 project completion is too late due to lack of resources, which refuses the management to approve that favored 112 project. On the other hand, under estimation may result in approval of projects that will fail to deliver the 113 expected product within the time and budget available [1]. So, there is a need of accurate estimation effort 114 technique at early stages of software development. In this research, the main aim is to improve software effort 115 estimation by using different training algorithms of Neural network. 116

The main reason for using such a learning system for this problem is to keep the estimation process up-to-date by incorporating up-to-date project data. At last Comparison is drawn between training algorithms used in this research to state that Bayesian Regularization gives much accurate estimation. One algorithmic approach, COCOMO is also compared with all three algorithms. For the sake of ease, tool is generated with the help of MATLAB. This has been shown in

¹²² 6 V. Proposed Methodology

123 7 D

For our work, we use feed-forward network with three different training algorithms: LM, BPA, BR. The Neural Network is implemented using 12 neurons for input layer, 12 for hidden layer and 1 for output layer. f) Performance Criteria Mean Magnitude Relative Error: MMRE is frequently used to evaluate the performance of any estimation technique. It seems obvious that the purpose of MMRE is to assist us to select the best estimation approach. It measures the percentage of the absolute values of the relative errors, averaged over the N items in the "Test" set and can be written as [18]: MMRE = {actual effort} -{estimated effort}]

¹³⁰ 8 VI. Experimental Results and Comparison

131 Neural Network trained by three different training algorithms, with same dataset i.e. NASA93.

132 9 Conclusion

Effort Estimation is one of the crucial tasks in software project management. This simulation with NASA93 dataset has been carried out using tool created with the help of MATLAB. Neural Network is trained using "trainlm", "traingdx" and "trainbr" algorithm. The result from our simulation shows that Bayesian

136 **10 Year**

137 Regularization gives the best performance, among the other training algorithms. We have experimented with 15

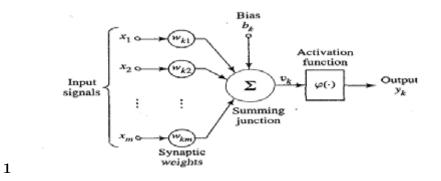

attributes of the COCOMO and further investigation can be done with other attributes and also concentration needed for process maturity. 12^{3}
