## Abstract

Hospital IT security presents many unique challenges that must be solved by the entire organization. Network and computer threats can cause thousands of dollars in lost time and resources, legal repercussions, and damaged reputation. Despite warnings from a wealth of public breach notifications, many hospitals are inadequately prepared to deal with today's computer-based attacks. This research explores the root causes of hospital network and computer in security, and addresses these problems with methods implemented in actual hospitals. A lack of comprehension of methods to assess and implement security measures by hospital IT security employees can hinder network visibility and prevent their ability to stop threats. In addition, these same people are unable to express security concerns in terms management can understand, harming their credibility within the business as a whole. Without this support, organizational change is impossible. By addressing these concerns with a combination of people, process, and tools, we can solve complex problems, protect patient data, and ensure IT operations so hospitals can serve their community and save lives.

---

*Index terms*— web filtering, e-mail filtering, system patching, antivirus, secure wireless access, firewall configuration.

## 1 Introduction

Securing a hospital network is challenging. Doctors and physicians often require special needs, and external vendor systems require agreements that pose restrictions on possible security controls. In addition, hospitals have many of the same challenges other organizations struggle with. Improper management of systems and network defenses can expose private information and credit card numbers to attackers. This can violate laws and regulations, cause negative publicity, impact the financial stability of the business, and hinder the ability to provide care to patients.

Effective security requires many working parts in an organization, not all of which are technical solutions. Defined process, skilled and well-managed personnel, and management support are vital aspects of security. Many hospitals fail to address one or more of these aspects, leaving their network open from multiple attack vectors.

Security breaches may also hinder a hospital's ability to adequately care for its patients, or admit new patients. Viruses and other attacks can cause medical record systems to be disabled, forcing hospitals to revert to a paper system and decreasing efficiency. In some cases, incidents can prevent hospitals from providing adequate care. In these cases, ambulances may have to be rerouted to other medical facilities in the area, losing business and endangering those who need immediate care.

## 2 II.

Defining 'Security'

First, when we refer to 'security' throughout this research paper, we are referencing IT security, not physical or some other type. Security is often defined as protecting the confidentiality, integrity, and availability of data,

43 but the interpretation and context of these aspects will change from organization to organization. Rather than  
44 creating an overall definition of 'security', we will define it in terms of several goals. When we refer to 'security'  
45 throughout this paper, we will mean technology, processes, procedures, and organizational structures that: ?  
46 Ensure the confidentiality, availability and integrity of electronic/digitized assets and data, especially PHI. ?  
47 Ensure the ability to provide quality care to hospital patients through the use of technology. ? Minimize the  
48 impact of security threats against the needs of the business. We hope to represent the flexible and intangible  
49 nature of security, especially in a hospital environment, by defining 'security' as a collection of goals, rather than  
50 an absolute state. As we will show later, security events can be quantified in terms of risk, which must either be  
51 accepted or not for each hospital dependent on individual tolerance. Some hospitals may accept more risk while  
52 defining themselves as 'secure', while others will accept less risk. It is not a term that can be absolutely defined,  
53 and we make no attempt to represent it as such. We simply present one useful definition for our purposes here.

54 Many approaches to network and computer security focus purely on better technology. By increasing the  
55 effectiveness of anti-virus, web proxies, intrusion detection, and other technologies, attacks can theoretically be  
56 prevented over the network. In reality, this is not the case. The true problem of network and computer security  
57 in hospitals is not with the current technology solutions available on the market. The problem is with the way  
58 security is understood, accepted, and implemented by the people within the hospital. Communication between  
59 security teams and1 ( D D D D D D D D ) Year 013 2 E

60 Abstract -Hospital IT security presents many unique challenges that must be solved by the entire organization.  
61 Network and computer threats can cause thousands of dollars in lost time and resources, legal repercussions,  
62 and damaged reputation. Despite warnings from a wealth of public breach notifications, many hospitals are  
63 inadequately prepared to deal with today's computer-based attacks. This research explores the root causes of  
64 hospital network and computer in security, and addresses these problems with methods implemented in actual  
65 hospitals. A lack of comprehension of methods to assess and implement security measures by hospital IT security  
66 employees can hinder network visibility and prevent their ability to stop threats. In addition, these same people  
67 are unable to express security concerns in terms management can understand, harming their credibility within the  
68 business as a whole. Without this sup-port, organizational change is impossible. By addressing these concerns  
69 with a combination of people, process, and tools, we can solve complex problems, protect patient data, and  
70 ensure IT operations so hospitals can serve their community and save lives.

71 upper-level management is a driving factor for this problem. As we will show, management support is required  
72 for any major change in an organization, because many security changes affect the entire organization. If this  
73 support is missing, many changes are ineffective or incomplete. Our approach seeks to address both the technical  
74 issues as well as communication issues. It meets the needs of the organization while defending its most important  
75 assets. It provides the flexibility and resiliency to cope with the changing world of computer and network  
76 security, and addresses the complex factors involved in security for a large organization. Our method contains  
77 multiple stages. First, hospitals must understand the specific challenges they face. Next, specific methods will  
78 be used for assessing a hospital's security and risk posture. Once these are complete, other methods can be used  
79 to consistently improve IT security in these organizations. In the final section, case studies will illustrate the  
80 success of the method. It was implemented in several hospitals who have all reached various levels of maturity.

81 IV.

### 82 3 Hospital Security a) Implementation

83 As discussed previously, security within an organization is a combination of people, process, and tools. Technical  
84 controls -tools -provide a means to restrict and regulate the network. Process defines standards by which  
85 the organization implements and enforces security controls. Finally, the people, including politics between  
86 departments, the culture of the organization, and simply their communication, are ultimately responsible for  
87 security. All three are necessary to protect the hospital network. The assessment phase helps the hospital  
88 understand its current security posture. Using the data obtained, security exposures can be identified, and  
89 then corrected. The methods described in this chapter include many specific technical controls that must be  
90 implemented to provide a reasonable degree of security. Beyond these controls, most hospitals struggle with  
91 communication and internal politics. Lower level security employees cannot communicate appropriately with  
92 upper level management, which will allow them to obtain the support they need for security initiatives.

93 V.

### 94 4 Specific Technical Controls

95 Every hospital must have a set of technical controls to protect their network. They must also have the proper  
96 personnel and management support to drive the change necessary to implement and enforce the controls. A  
97 list of controls have been defined below that will drastically improve security for most hospitals. Each of these  
98 controls can be implemented in many ways. No particular vendor or implementation is recommended, although  
99 several are mentioned as examples. These are details that must be worked out for each individual hospital to  
100 solve their specific needs.

---

## 101 5 a) Web Filtering

102 The majority of successful attacks today expose vulnerabilities in web browsers. These can be attacks against  
103 the browser itself (such as Internet Explorer or Mozilla Firefox), but they can also exploit other services utilized  
104 by the browser such as Java or Adobe Flash. As such, normal web browsing creates a large security risk for any  
105 hospital. To help protect against these specific attacks, web filtering appliances can be purchased from many  
106 vendors. It is also possible to use an open source tool, such as Snort, to create a custom web filter, but most  
107 organizations opt to purchase a pre-built solution.

108 Control 1: All web browser traffic must be filtered through a web gateway or proxy appliance.

109 Web filters generally work using blacklists. This approach blocks specific web traffic based on content  
110 signatures, DNS name, IP address, or other static rules. Any traffic that does not specifically match is allowed by  
111 default. Some web filters act as an enterprise-wide antivirus solution. For example, McAfee's Web Gateway [19]  
112 searches for content matching known viruses. Due to the prominence of attacks originating from web browsing,  
113 a web filter is absolutely necessary for any hospital.

## 114 6 b) Email Filtering

115 The primary responsibility of an email filter is often to reduce or eliminate spam for an organization, and minimize  
116 viruses and other threats. Email attacks can trick a user into opening a malicious web link or attachment, but  
117 they can also attempt to get a user to divulge sensitive information. To prevent most spam and malicious  
118 emails, we can use a dedicated email filter, such as Cisco IronPort [9]. Microsoft Windows is not the only attack  
119 surface that requires regular patching. Adobe products (Flash, Acrobat Reader, Shockwave, etc.), Java, Apple  
120 Quicktime, and any other popular software are often discovered to have severe security vulnerabilities as well.  
121 Other operating systems, such as many Linux variants or Mac OS X release patches for newly discovered security  
122 vulnerabilities, although these are exploited less often due to a smaller user base. Finally, many medical system  
123 vendors prohibit hospitals from installing patches on their computer systems, even if the hospital owns the system.  
124 They instead require the hospital wait for the vendor to patch the system for new vulnerabilities. Unfortunately,  
125 many of these systems never get patched once they are installed in the hospital environment. To combat this,  
126 other controls must protect these systems, such as network segregation and strict policy surrounding their usage.

## 127 7 d) Anti-Virus

128 Anti-virus is primarily the last defense against an attack. When all other controls have failed, a local antivirus  
129 installation can detect and block malicious code before it is able to compromise and infect a system. When  
130 referring to 'anti-virus' in this paper, it should be considered a program which tries to detect and prevent any  
131 type of malicious attack on an end-point system. This can include Trojan Horses, viruses, worms, adware,  
132 spyware, and any type of attack normal enterprise antivirus can detect and prevent. Anti-virus is most useful  
133 on Microsoft Windows computers. Solutions do exist for Linux and OS X, such as ClamAV [10] for Linux and  
134 Sophos [33] for OS X, but they typically provide less value to hospitals, who have a high number of Windows  
135 systems in the network environment.

136 Control 4: Anti-virus must be installed and up-to-date on end systems.

137 Anti-virus should be installed on any Microsoft Windows system with adequate resources. Administrators often  
138 forgo installing it on high load servers for fear it will adversely impact performance. This is a risk that can be  
139 accepted provided other controls protect the system. Like system patching, many medical system vendors prohibit  
140 hospitals from installing anti-virus solutions on their systems. Their reasons include performance concerns and  
141 unintended side effects. When this occurs, other controls must adequately protect these systems. The hospital  
142 should ensure that anti-virus is updated regularly to the latest software versions. This includes the anti-virus  
143 installation itself, but it also includes virus signatures released regularly from the vendor. This ensures the system  
144 can be protected from the latest known threats. Despite providing a valuable control, anti-virus is still limited  
145 by its signature definitions. It can only detect and protect a system from known threats. Polymorphic viruses  
146 and new attacks will bypass anti-virus and are still capable of compromising a system.

## 147 8 e) External Device Control

148 Any device capable of easily and physically carrying data inside or outside the hospital network can be classified  
149 as an 'external device'. This includes both hospital provided and personal laptops, and removable media such  
150 as USB flash drives or external hard drives. These devices can be connected to insecure networks outside of  
151 hospital control, which can cause them to become infected with a virus or other malicious software. Upon  
152 returning to the internal hospital network, the malicious code can then attack the internal network and company  
153 resources. Hospitals should also be concerned with data ex-filtration. A laptop is capable of carrying PHI  
154 outside the network, which can lead to a security incident if not adequately controlled. Even though we are able to  
155 apply patches that correct these vulnerabilities. Figure 1.3 shows the number of vulnerabilities released per  
156 month for Microsoft products that were rated 'Consistent Exploit Code Likely' by their Exploitability Index [20].  
157 This rating means 'analysis has shown that exploit code could be created in such a way that an attacker could  
158 consistently exploit that vulnerability.' [20] Also included is a tally of those vulnerabilities that were being actively  
159 exploited on the Internet at the time Microsoft released the monthly bulletin announcing the vulnerabilities. [21]

160 This measurement shows that sometimes a vulnerability is being exploited before a patch is even available. This  
161 increases the urgency for applying a patch to vulnerable systems.

162 Control 5 : Only hospital provided and controlled PCs should be allowed to connect to the internal network.  
163 USBs and other forms of removable media should be tightly controlled, and ideally completely restricted.

164 While company policy can provide some mitigation of this threat, it may not be a strong deterrent for many  
165 employees or other outside personnel (consultants, guests, etc.). Effective technical solutions tend to be expensive  
166 and difficult to implement. One example is Cisco's Network Access Control (NAC), which is certainly expensive,  
167 but when configured properly can protect against external devices.

168 Laptops and other hospital resources (hard drives, USB sticks, etc.) carrying sensitive data must be fully  
169 encrypted if they can be taken outside hospital property. This is especially important for laptops or any device  
170 that may be a target for thieves. Many HITECH breach incidents[14] were related to stolen hard drives, USB  
171 sticks, or laptops containing personal data. In such cases, companies must disclose the data loss to the public, and  
172 then pay for remediation. With encryption, the only loss is the physical hardware. Control 6: External devices  
173 storing sensitive data must be encrypted. f) Secure Wireless Access Wireless access points provide convenience  
174 for hospital employees and outside guests. The signal for access points is broadcast over the air, which can allow  
175 anyone within range to view and attempt to connect to the network. Without proper controls, an intruder could  
176 gain access to sensitive resources or disrupt network operations. Primarily, employee wireless access should be  
177 encrypted with enterprise WPA2 using a central RADIUS (Remote Authentication Dial In User Service) or  
178 AAA (Authentication, Authorization, Accounting) server. This provides a strong level of encryption and allows  
179 employee access to be controlled with a central server. Guest wireless access is typically unencrypted and open  
180 in most hospitals. This allows anyone, even attackers, to connect to the network. To prevent a malicious user  
181 from compromising the internal hospital network, the guest network should be on a completely separate network.  
182 Without restrictions on the guest wireless network, employees can also connect to this open network and bypass  
183 normal internal network filters (such as web filters or tight firewall rules). This can lead to employees accessing  
184 Internet resources that should be restricted. It is also possible external users can detect and attack an employee  
185 system connected in this way. To prevent this, WPA/WPA2 encryption should be enabled on the guest network,  
186 even if it uses a simple and publicly available encryption key. Employee systems should also be denied access to  
187 this network by using a network access control tool like Cisco NAC.

### 188 9 g) Firewall Configuration

189 Numerous resources exist explaining how to properly configure an enterprise firewall for security. This is only  
190 mentioned for posterity. Firewalls should be configured as restrictively as possible. Internal systems should not  
191 have unrestricted access to the external Internet. Direct access from the external Internet should be prohibited  
192 to the internal hospital network. A demilitarized zone (DMZ) should be designated for allowing external Internet  
193 access to resources hosted on the hospital network. The DMZ must be restricted from accessing the internal  
194 network.

195 Control 7: Firewalls should be properly configured to be as restrictive as possible.

## 196 10 VI. Other Controls

197 Most hospitals struggle to implement and maintain even basic controls, and the broad range of controls we listed  
198 above attempt to solve the most common areas of exposure. They should be implemented on any hospital network.  
199 However, many other controls should be used to provide more granular protections. As an example, passwords  
200 should be complex and changed regularly (as defined and accepted by company policy). This is a minor control  
201 that can be implemented with Microsoft Active Directory, and its definition can change per individual hospital.  
202 There are different ways to provide authorization to resources, such as Active Directory for network shares, or  
203 specific configurations for individual systems. Generally, users should be given minimal access to the resources  
204 they need to do their jobs. External Internet access should be restricted, internal server resources should be  
205 restricted, and individual workstation access should be restricted. By providing minimal access, we limit the  
206 exposure surface of the hospital computer and network resources. Technical controls help protect the hospital  
207 network. However, they are only one aspect of securing a network. The next section will discuss the Ideally, in  
208 the case of an external laptop or other computer, a technical solution will detect an attempt to connect to the  
209 network. It will then run through a series of checks before allowing the device to communicate with the rest of  
210 the network. These checks can include system patch levels, anti-virus installation and version, and other software  
211 checks. If the system passes, it is allowed to connect. If not, it must correct the problems before it can access  
212 the internal network. To correct the problems, a separate VLAN is often utilized to allow the user to download  
213 patches or other requirements. Software controls can be used to prevent users from using unauthorized external  
214 media. Super glue can also physically seal the USB drives of a computer, although we do not recommend this.  
215 human aspect of security, which must be successful in order to meet the constantly changing security world.

## 216 11 VII. Security Personnel

217 The technical controls in the previous section provide strong protection against many forms of attack, but it is  
218 equally important to address the people side of security. Politics between differing groups and individuals, as well

---

219 as the culture of the organization, play a role in security. Individual knowledge and skill are important as well.  
220 Hospitals are no different than any other organization in this manner. Low level security personnel are essential  
221 for implementing and maintaining security controls and providing creative solutions to problems. In addition,  
222 management must actively support and enforce security initiatives. The interaction between these groups has  
223 an effect on how security is implemented within the hospital. In this section, guidelines will be provided for  
224 structuring the security of a hospital. Also, when groups within an organization communicate effectively, they  
225 can solve security problems.

## 226 **12 VIII. Security Team**

227 The security team is tasked with administering and reviewing the security systems at the hospital. Not only  
228 do members of the security team configure and maintain appliances, systems, and security software throughout  
229 the organization, but they must also review logs and other reports for security incidents. They think and make  
230 decisions about security for the hospital, although final approval may defer to a manager or director. Members  
231 of the security team generally administer major security systems at the hospital such as firewalls, web filtering  
232 appliances, email and spam filters, IDS/IPS appliances, vulnerability scanning, central logging systems, anti-virus,  
233 and patch management systems. In many cases they will have other responsibilities that may or may not directly  
234 impact the security of the organization. Hospitals often do not have the resources to have dedicated security  
235 personnel without other responsibilities. In many cases, the members of the security team will not be directly  
236 responsible for administering a system that has an impact on security. This could be a weakness discovered from  
237 a vulnerability scan, a new web server that will be placed on the DMZ, or any number of IT operational items.  
238 When this occurs, members of the security team must work with other members of the organization to implement  
239 or maintain a system. They can provide advice on the security of the system, as well as test it to ensure it functions  
240 as intended. Good interdepartmental relationships are vital for this to be a success. When dealing with another  
241 department the security team will often rely on their manager or director. In some cases, a formal security team  
242 has not been established for the hospital. If this is the case, a security team should be created. When selecting  
243 team members, choosing personnel who already administer many of the devices and systems mentioned above  
244 can be a good idea. However, this selection is often decided by an already existing IT manager. The members  
245 must be trustworthy and reasonably knowledgeable about security. The team must also include a manager with  
246 the authority to make decisions acting the network infrastructure of the organization, and he or she must also be  
247 able to raise concerns with higher level management when necessary. When a team is established, they can begin  
248 to discuss and handle many of the responsibilities required of this team. Weekly meetings are often worth-while  
249 to ensure that everyone and the manager is on the same page. Formal policies must also be defined around this  
250 team and they must work with the organization to get these policies and responsibilities accepted. The security  
251 team is also responsible for thinking about and solving IT security problems for the hospital. Some problems  
252 may be directly solvable by members of the security team, while others must be delegated to outside groups  
253 through management. For example, a security team member may be directly responsible for the management of  
254 the hospital firewall, and can make any adjustments as necessary. This depends on the expertise of the individual  
255 team members. In some cases, the security team may only need to provide recommendations to other groups  
256 within the hospital. The security team should meet regularly, usually once per week. In each meeting the security  
257 team should assess the current state of computer and network security for the hospital, then address any new or  
258 ongoing initiatives. The team should always explore ways to improve the hospital's security, even if improvements  
259 are not forthcoming. It is then the manager's responsibility to best utilize the resources at his disposal and drive  
260 the initiatives of the security team.

## 261 **13 IX.**

## 262 **14 Management Support**

263 Strong and efficacious network security begins with management support. The security manager oversees the  
264 security team and is responsible for ensuring resources are focused where necessary. This can be a balancing  
265 act between security responsibilities and normal IT responsibilities. The manager must also ensure that team  
266 members are consistently reviewing security data and reports so incidents are noticed and duly investigated. The  
267 security team must be supported further by an executive at the director or higher position (like Chief Information  
268 Security Officer). The director must handle funding for the security program. They must also understand IT  
269 security risk and be able to present this effectively to the rest of the organization. Most importantly, they must  
270 help the security team navigate Year the politics and culture of the entire hospital. Without support from the  
271 rest of the organization at a high level, the security team will be hindered during investigations and response,  
272 they will not be able to enforce policy, and they will not get proper funding. Management support is required  
273 to get the resources necessary, both in personnel and monetary, to efficiently and effectively deal with security  
274 problems. Their support is also needed for policy change and enforcement. "Those with the power to allocate  
275 resources, both financial and the time of employees, can control any change expressed from lower in the power  
276 structure.

## 15 Conclusion

277  
278

290

Hospitals have many of the same IT security problems experienced by other organizations, but with added complications from doctors, external vendor systems, patient records, and specific legislation. They also struggle with insufficient resources and often lack comprehensive expertise to cover all areas of security. Ineffective communication between low level security personnel and management can cause misplaced priorities and misguided initiatives. Securing a hospital network requires a combination of technical controls, policies and processes, and responsibility among the people of the organization. By first understanding the hospital network and its resources, then by quantitatively measuring the IT security risk and understanding areas of exposure, a strong security strategy can be created and supported by management, the security team, and the rest of the organization. Finally, security must be continually assessed and reassessed. With new and innovative threats, effective security cannot remain stationary. It must constantly evolve to meet new challenges. IT security for hospitals cannot be solved with a simple approach and a single piece of technology. It is an entire process among many people within the organization. By addressing these problems as they are -complex and multi-tiered -the confidentiality, integrity, and availability of computing resources will be ensured. This will allow the hospital to function normally as a business and serve patients effectively and with privacy. <sup>1</sup>
