An approach for exposing legacy applications for integration in modern enterprise business processes

Received: 19 April 2011 Accepted: 9 May 2011 Published: 19 May 2011

6 Abstract

3

Organizations have legacy software applications and systems, which are valuable assets and still critical to their current business operations. One of the key challenges for today's 8 enterprises is how to effectively and efficiently integrate these legacy assets with other. 9 internal and external applications and business processes. Modernizing legacy systems using 10 SOA may help an organization to meet the increasing demands of the business processes 11 integration while maintaining its large investment in legacy systems. SOA bridges the gap 12 between business processes and technology resulting in improved reuse of existing applications 13 and interoperability of desperate applications. Sometimes it is required to integrate legacy 14 system with other application in a short span of time. As per the business requirements 15 although SOA may address the solution, but it is very difficult to integrate due to several 16 issues in service identification and mapping in legacy application and business processes. In 17 this paper an approach is proposed for participation and alignment of legacy applications in 18 the enterprise business processes in a short span of time with the help of business process 19 modeling and SOA, incorporating both Top down and bottom up approach together. As a 20 case study, the paper describes the exposure of a prototype legacy banking application for 21 participation in a service-oriented architecture. The paper also proposes a novel way of 22 determining the key business logic and resources embedded in a legacy C/C++ application 23 with a reverse engineering approach so that the SOA mapping is automated and the 24 constraints like memory and processing can be analyzed. 25

26

²⁹ 1 INTRODUCTION

usiness organizations have a large investment in software written in legacy programming languages and architecture. Today, most of the organizations run systems that have been developed a long time ago and are still adapted and maintained to meet current needs [1]. Approaches used in legacy systems sometimes differ considerably from today's modern paradigms. Adapting legacy software systems to new requirements also requires their migration and integration with new technologies and applications.

A Legacy Information System can be defined as "any information system that significantly resists modification and evolution" [1]. These Information Systems pose considerable problems including brittleness, inflexibility, isolation, non-extensibility, lack of openness on the enterprise IT infrastructure. They significantly resist further modification and evolution. Legacy systems were designed for internal, enterprise wide usage while today's enterprise demands for inter enterprise communications and support for agile business processes.

There are various methods proposed including supplementing or replacing restrictive legacy applications and technology with newer, open standards-based applications and technologies, but still retaining existing business functions [2]. Legacy renovation is an expensive task. As the requests for modifications, new development and

Index terms— Legacy Applications, W eb services, Integration, Service oriented architecture, business
 process modeling.

3 BACKGROUND INFORMATION

integration accumulate, it is very difficult to keep pace and enable a more agile enterprise. So it is advantageous
to integrate legacy application with new applications while retaining the business logic intact.

45 SOA models the enterprise business workflow as a collection of business services, these services can be easily

Reused and integrated in the organization to address the application requirements [3] [4]. Rather than developing

47 from the ground up every time a change is needed, new assets can be created easily from existing services, saving
48 time and money ??5]. The most important advantage of SOA is to provide a data bridge between incompatible
49 and desperate technologies [6].

BPM is a set of technologies and standards for the design, execution, and administration and monitoring of complex, automated business processes BPM provides the facility to monitor, analyze, control and improve the execution of these processes in real time [7]. Existing Web Services can be integrated as the counterparts of steps in business processes. Examples are credit verification in an on-line order process [8].

Several approaches for Legacy application integration and migration towards Service oriented architecture have been proposed in the past but they B ©2011 Global Journals Inc. (US) include difficulties in identifying candidate services from legacy application and their alignment with the organizational business processes requirements.

57 Wrapping functions of legacy systems for exposing as web services may be a fast way for migration towards SOA,

58 However the services provided are technology oriented and do not fully address business goal or scenario, which

⁵⁹ might lead to the services not being fully utilized as per the business goals. The top-down approaches analyze ⁶⁰ existing business processes in order to identify adequate services but services are business oriented and may failed ⁶¹ to get the needed functionality in largery applications.

61 to get the needed functionality in legacy applications.

Our proposed method uses BPM and SOA together in order to make legacy participation in the enterprise business processes by means of exposing and orchestrating services. We used both top-down BPM driven and bottom up SOA driven service identification mechanism along with automated discovery of business logic in legacy codes to better align legacy application with business needs.

The reminder of the paper is organized as follows: Section 2 provides background information needed to understand the paper, Section 3 presents the proposed approach for legacy service exposure and participation in

enterprise business processes with a case scenario, section 4 describes Discussion of result and historical approaches
 for legacy system migration and integration. We conclude with summary and future directions in section 5.

70 **2** II.

71 3 BACKGROUND INFORMATION

An organization has a collection of interrelated business processes, which consist of a series of activities, jointly represent a business goal. For instance an order process in a B2B environment includes several activities networked with each other to complete the order process business goal. These business processes may have their span in

⁷⁵ several desperate applications in the enterprise and beyond.

The "service" is an application logic or underlying computing resource with an abstraction of the underlying implementation [3], that is exposed through an interface and which can be invoked over a network with standard protocols [9]. The most important application of SOA is to align the services to the business requirements and to

facilitate reusability of existing services connecting the various operational systems that automate an enterprise's
 business processes [10].

Bottom-up approaches examine legacy systems and standard software for the identification of services. The bottom-up approach analyses the existing application for all available functions that can be exposed as a web service. With a bottom-up approach the definition of services originates in the domain of the application [11]. This approach results in a large number of available functions which can be exposed as services but does not tell anything about their usability. In bottom-up approach Services are discovered, rather than defined as requirements, therefore it tends to lead to poor business services as it preserves the current solution instead of addressing business needs.

The top-down approaches analyze existing business processes in order to identify adequate services. This approach looks at the processes in the business domain, decomposes them into sub process/tasks/functions until 'logical units of work' are defined, which we call services. The decomposition of the process in itself is not enough to discover services, because we will have to convert the 'candidate-service' into a real-world executable and discoverable service. This means we have to compare the functionality of the service with the available infrastructure but it does not reach deep into the architecture and implementation domain.

94 By combining these two approaches together we may get the best of both eliminating the shortcomings of 95 each one and integration with the current application infrastructure and readiness for the business needs we 96 are looking for. Therefore, a hybrid approach combining both methods is applied in order to minimize the problems associated with these approaches [12] [13]. The hybrid meet-in-the middle approach combines top-down 97 and bottom-up techniques in order to identify services that better correspond to both the business requirements 98 and the existing systems [14]. It provides a compromise between the top-down and bottom-up techniques that 99 eliminates the most significant disadvantages. We proposed a meet in the middle approach with automatic 100 discovery of prospective services in the legacy application for integration in business processes. 101

III. 4 102

PROPOSED APPROACH 5 103

The proposed approach is a combined meet in the middle approach consists of BPM and SOA along with the 104 reverse engineering of legacy application in order to identify the candidate services and their participation in the 105 enterprise business processes. It eliminates the disadvantages of failure in getting the needed functionality in 106 legacy applications and lengthy time of top down approach and non-business orientation of bottom up approach. 107 Basically, we are proposing consolidated approach that provides guidance on the derivation of both business 108 services and supporting software services to achieve a close business and IT alignment. The proposed method is 109 influenced by meet in the middle approach by Inaganti and Behera with some improvements by minimizing the 110 problem in finding of candidate service in legacy application [15]. 111

This approach requires a comprehensive analysis of the legacy application and not just the mapping. In this 112 paper we also presented a reverse engineering approach to extract the information of the legacy application 113 through resource extraction from the application along to generate and publish the service. 114

The proposed technique can be summarized as a methodology for mapping legacy application resources 115 to modern enterprise environment by BPM and SOA with the help of Reverse Engineering to facilitate the 116 identification and extraction of the key business logic from Legacy application and alignment with business 117 requirements. Figure 1 shows the block diagram of proposed method. As an example scenario, here we introduced 118 a prototype legacy banking application developed in C++. The Application is a monolithic standalone C++ 119 application with no external interface for communication with other applications. The application stores the data 120 121 in flat file system and provides various inbuilt functionalities like opening an account, deposit money, withdraw 122 money, get balance, viewing of transactions and various reports. One can interact with it only through application GUI which is inbuilt in the code. 123

We assume that there are certain situations arises due to business needs, in which above application is required 124 to be integrate with some other modern applications and business processes. As stated earlier in the paper, it 125 is not viable to replace or rewrite the legacy application with new code. As the legacy application is standalone 126 and the logic is embedded deep in the form of functions, it is very difficult to handle this situation. Our approach 127 resolves the problem without rewriting the legacy code and without interrupting the operation or maintenance 128 of the legacy system. 129

We presented a business process of ATM here. The ATM process resembles the new business requirement and 130 we have to address it by using core business logic of legacy application. The ATM application will be a thin 131 client with only GUI. The ATM GUI will provide only the user interface and the orchestrator takes care of proper 132 sequencing of operations and calling of web services from legacy application. Various new business conditions 133 and constraints, which are not present in legacy application may be addressed with the orchestrator, for example 134 prohibiting withdraw operation in case of insufficient balance or not allowing a certain transaction if the number 135 of transaction exceeds, without rewriting of the core component of the legacy application. The methodology is 136 mentioned in following steps. Analyze the Core Business process. 137

In the first step, it is necessary to analyze functional domain of business process and understand the business 138 requirements. During the initial analysis phase, basic decisions regarding identifying the most important functions 139 of the domain and showing their interrelationships is identified. The business structure and the functions of the 140 business process are specified [16]. A business process reveals how an individual process activity is linked with 141 another in order to achieve a business objective. We have to identify the start and end events of a particular 142 business activity, human interactions with the process, automated activities and links with the other applications 143 and organization's processes. This step results in a core coarse grained business process. This analysis results in 144 the development of the "to-be" process model that an SOA solution is intended to implement [8]. 145

In the context of our scenario we analyzes how a user will interact with ATM, how the business process will 146 progress with the user interaction. This step results in the use case of ATM process, actors, activities and the 147 flow of business. 148 ii.

149

Model the core business processes 6 150

In this step we design the core business process found in previous step into a graphical model using a BPM 151 modeler, as in our case Intalio [7]. At first, the business process is modeled at a high level where activities in 152 the Business Process Diagram usually aggregate sub processes, which are graphically evaluated in another sub 153 process BPM diagram. A [+] sign inside an activity denotes a process that can be decomposed into sub-processes 154 [17]. We marked each task which requests an external service as service task. One of the purposes of the process 155 156 model is to define process execution and to create the BPMN notation for this purpose.

157 The BPMN defines both the graphical notation and the semantics of a Business Process Diagram, We model the diagram with core elements of a BPD which comprises Flow Activities, Tasks represented by a rounded-corner 158 rectangle which is a generic term for work that has to be performed, Events which are diagrammed as a circle, 159 Gateway Objects represented by a diamond symbol which are used to control the divergence and convergence of 160

a sequential flow. By means of these basic Flow Objects. The core process contains at least one POOL which is 161

executable and can be deployed on orchestration Engine. 162

10 IDENTIFY THE POINT OF FUNCTIONALITY IN LEGACY APPLICATION

The core business process acts as an orchestrator which will direct and invokes the various Web services from legacy and other third party applications to form and execute a complete business activity [18]. iii.

¹⁶⁶ 7 Business Process refinement

In this step we perform decomposition or refinement of sub processes of core BPM Diagram into elementary or 167 atomic business functions. Business process refinement identifies service tasks, message activities, and events and 168 actions in the sub process [11]. When the business process is subdivided into sub-processes or decomposed into 169 granular activities the lowest level tasks will consist of small, cohesive "logical units of work", that are supported 170 by the functionality offered by distinct services. It results in discovery of elementary business functions which can 171 be addressed by web services in the application domain [19]. Delegating functionality into sub business processes 172 prevents business processes from becoming overly large, complex and difficult to maintain. The refinement can 173 be seen in authorization process diagram. 174

After refinement of sub processes the next step is to find out the Service Tasks which provide some sort of service which could be calling a Web service or an automated application. We will find the task which will call the legacy and other web services process. This service tasks will call atomic (single) web service interfaces of legacy application.

In the case of authorization sub process the call authorize task invokes the authorize function of legacy application as shown in yellow color in figure ??.

¹⁸¹ 8 c) Existing asset analysis and Service identification in Legacy ¹⁸² Application

The purpose of this step is to identify assets in the legacy application i.e. business logic and legacy functionality which are capable of supporting the realization of services that meet business needs. The focus is on existing assets that play a role in business processes 14]. We initially perform a coarse-grained mapping of business processes and process activities to the portfolio of existing applications and application interfaces. Later in the specification, we perform a more fine-grained mapping, including message specification. We also identify various system resources so that the performance can be measured. i.

¹⁸⁹ 9 Component identification in legacy application

Service identification On the one hand, it is to determine what business functionalities should be provided by the target service in the application domain. On the other hand, the business functionalities embedded in the legacy system should be identified in order to be reused in the target service [20]. In this step the legacy application will be reverse engineered and we will find the various resources and embedded business logic to be exposed as web services by adopting bottom up approach. The analysis reveals the reuse potential of existing legacy components. The results of this step include information on system architecture, system components, infrastructure details and interfaces.

The proposed work identifies that this is a tedious process and the complexity grows with the line of code that reflects the business logic. Therefore a summary of the business logic present in the code is of extreme important. Here it is performed by a automatic reverse engineering tool. The working description of the tool is as given below.

First the tool Scans the program and tokenizes the program. Thereafter it removes the comments and blank sections. It Extracts the function definitions and other resources using following logic:-1. Check if there is a "(" token in the line or not If so, extract the previous token (which can be function name or a predefined function or key words like if, for and so on) 2. Check if the token is a key word or not. If not, scan till the end and look for a ";" if it is not there, scan for another token appeared before the current token with space separation. 3. If the previous token is a key word (which reflects the return type) then marks the current line as the function definition. Extract the arguments and return types.

An approach for exposing legacy applications for integration in modern enterprise business processes ©2011

²⁰⁹ 10 Identify the point of functionality in legacy application

210 In the previous step we found the information about application resources and various functions present in 211 the Legacy application through reverse engineering. Now we identify the points of functionality of the legacy 212 application that may be useful to implement the needed web services to interact with service task in the 213 Orchestrator [15]. In the output of automated tool we find the independent functions calls so that it can be 214 used to designate or make as a point of functionality, it means, among several functions we found the one that contains the functionality of interest for service tasks found in top down approach. For example found_account 215 function may be used to make authorize function wrapper that can be used as point of functionality and can be 216 exposed as web service and mapped with service task. 217

218 iii.

219 Exposure of identified functions as web service.

The functions identified in previous step as the point of functionality are now exposed as web services [19]. 220 The Service interface defines the types of messages and the message exchange patterns that are involved in 221 interacting with the service, together with any conditions implied by those message. The definition of functions 222 223 which has to be called by service task has been written in a single header file test.h. The header file guides the GSOAP tool to generate stubs for needed web services. Now we write the web service module by using identified 224 functions of previous step and with the help of GSOAP supporting files. All the exposed web services can be 225 called through the WSDL Interface and the Service end point URL [20]. WSDL describes the operations that a 226 service can support, and the parameters each operation accepts and returns. End point URL serves as a service 227 provider. The application web service will provide the response to service task upon calling with appropriate 228 parameters. Figure 4 describes the wsdl portion for input and output parameter for Authorize operation. The 229 service matching activity maps the service task to corresponding atomic web service in the application layer. 230 Each atomic service task exactly maps single web service [15]. There may be some situation in which a service 231 task will be divided in more than one service task and it may comprised of more than one point of functionality. 232 We will map the service accordingly, for example the fund transfer service task will be associated to two services 233 i.e. deposit and withdraw. Several service task may be associated to same service, for example a withdraw service 234 235 may be associated to both withdraw and fund transfer service tasks. These concepts can be seen in Fig 1 and Fig 6. 236

At the end of this step we complete the matching and mapping of all the service task and corresponding web services with each other.

²³⁹ 11 e) Service realization and orchestration

All the web services exposed from legacy system were atomic and asynchronous, that means there is no such execution or sequence order is set by default. In a business process there are several operating conditions upon which a business activity relies. For example a withdraw service can only be happened after authentication service, it must not happened before. Assembling services in order to accomplish business logic and business processes is called orchestration. [3] Explains orchestration as "the implementation of a business related workflow owned by a single entity through the combination of business relevant services". The orchestrator is deployed as a BPEL program in the Orchestration director engine.

In this step we define orchestration logic as the business logic that sequences, coordinates and manages conversations among Web services. This entire thing is expressed in BPEL. To execute a BPEL process a BPEL engine is needed which parses the BPEL code and executes the contained instructions. The Core Web services that are used by the BPEL program have to be deployed in advance. The whole orchestrator is deployed on Intalio BPMS server which acts as an Orchestration director engine. The orchestrator may be called in presentation mechanism through its WSDL and endpoint URL. In the ATM application a Java GUI reforms the presentation task which uses the orchestrator.

12 DISCUSSIONS AND RELATED WORK

The implementation and results of the proposed method may be understood by following demonstration of the case scenario. In figure 5 an account summary page is displayed. We can understand that all the logic is embedded deep in the code of legacy application.

In figure 6 the composite fund transfer service task in the orchestrator is elaborated. New business process requires a fund transfer mechanism, which needs to be achieved from the existing code. This is done in the modeler by calling and sequencing two web services from legacy application thus making a composite process. In the sample banking application no individual authentication is required as the software interacts only through its GUI and it is accessed by bank authorities. But as per the requirement of ATM business process as the application is exposed to an external world then it is very important to put an authentication mechanism. This is incorporated in the orchestrator as shown in figure ??.

The results demonstrate the process proposed in this work with a sample banking application as elaborated 265 in the case description. The system can map legacy application at par with the requirement of business using 266 exposure of functionality through web services and the usability by orchestration of BPM process. Further the 267 released services can be used by any language or application like Java and C# through the service description. 268 This also proves that by adopting the proposed technique one would be able to integrate new logics with the 269 270 existing business logic or would be able to seamlessly upgrade the existing services without having to make any 271 changes in the coding in the legacy application. Therefore the architecture minimizes the maintenance cost by 272 maintaining the business logic in the middle layer independent of the implementation.

In the past several methods for legacy system modernization have been proposed and discussed. [21] elaborated the white-box modernization and blackbox modernization approaches comparisons.

Fig. ?? Intalio ATM orchestrator process with interfaces [22] Proposed a method to address the issues on migrating legacy systems into a Web enabled environment by using CORBA. [23] Used reverse engineering techniques to encapsulate the logic with JNI wrapper. [24] Proposed a method to make interactive legacy systems accessible by wrapping interactive functionalities. [25] Proposed a tool based approach to wrap the legacy codes. All of the methods were focused on the application modernization only rather than addressing thebusiness domain. In our approach we emphasized on a close business and IT alignment.

²⁸¹ 13 V. CONCLUSION

In this work a legacy application mapping technique by combining top-down approach with bottom-up approach 282 is proposed using SOA and BPM. The method defines how a legacy application should be exposed as services 283 and how these services can be used to fulfill business goals. The solutions principles are demonstrated through 284 the results. Instead of using the manual functionality discovery in the legacy service identification stage, a tool 285 is developed to automatically identifying the services. The interoperability of the entire solution is shown in the 286 result section. The prime criteria and objective of the work has been to prove the proposed design of legacy 287 application mapping and integration to participate in enterprise business processes. As the services are exposed 288 to be used on network, performance calibration and tuning is another aspect and the speed and processing 289 capabilities of the environments used must be taken into consideration. The proposed approach performance and 290 speed issues are some of the work that can be associated with the future direction of research for this work.
