7 Abstract

With end users demanding faster response time and management demanding lower costs and 8 more flexibility, Service Oriented Architecture (SOA) projects are becoming more complex 9 and brittle. Proper costing and identification of feasible benefits of SOA projects are quickly 10 becoming a significant influence in the mainstream of all industries. SOA is intended to 11 improve software interoperability by exposing dynamic applications as services. Current SOA 12 quality metrics pay little attention to service complexity as an important key design feature 13 that impacts other internal SOA quality attributes. Due to this complexity of SOA, cost and 14 effort estimation for SOA-based software development is more difficult than that of traditional 15 software development. Unfortunately, there is little or no effort about cost and effort 16 estimation for SOA-based software. Traditional software cost estimation approaches are 17 inadequate to address the complex service-oriented systems. Although numerous sources 18 expound on the technical advantages of SOA as well as listing praises for their intuitive and 19 qualitative benefits, until now no one has provided a reliable and quantifiable result from SOA 20 implementations currently in production. This paper proposes a novel framework based on 21 Work Breakdown Structure (WBS) approach for cost estimation of SOA-based software by 22 dealing separately with service parts. The WBS framework can help organizations simplify 23 and regulate SOA implementation cost estimation by explicit identification of SOA-specific 24 tasks in the WBS. Furthermore, both cost estimation modelling and software sizing work can 25 be satisfied respectively by switching the corresponding metrics within this framework. We 26 provide an example case study to demonstrate proposed metrics and we also investigate the 27 benefit of SOA to its adopters. 28

29

Index terms— Service-Oriented Architecture (SOA), Software Cost Estimation, Work Breakdown Structure
 (WBS), Framework, Return on Investment (ROI).

32 1 INTRODUCTION

well-developed understanding of the Return on Investment (ROI) for SOA has been a complex undertaking 33 34 [1]. This is due in part to the deficiency in comprehensive historical data on which to base any such model. 35 For the most part, SOA often exist as pilot projects than as full-blown production systems, and even those rare production-quality systems that do exist are too new for use in understanding critical issues to the ROI equations, 36 such as reusability and redeployment. Most organizations that want to build an SOA don't have a clue on how to 37 approach the cost estimation process. In many cases, they grossly underestimate the cost of their SOA, hoping 38 the management won't notice, this is done to get approval and reveal the higher costs later after investment may 39 have been made and too late to go back. This is not a good management practice. The other problem militating 40 against building a comprehensive cost model for SOA is the need to separate the service cost that results in 41

42 SOA from any well-designed application and the specific or incremental cost that obtains from a well designed

43 SOA application built on services architecture. Software cost estimation for Service-Oriented Architecture (SOA)
 44 development confronts more challenges than for traditional software development. One of the main reasons is the

⁴⁵ architectural difference in SOA compared to traditional software development. Josuttis [2] has pointed out that

46 distributed processing would be inevitably more complicated than non-distributed processing, and any form of

47 loose coupling will increase complexity. Meanwhile, the more complexity involved in a system, the more difficulty

the designers or engineers have to understand the implementation process and thus the system itself [3]. In other words, people have to devote more effort to accurate manipulations when performing more complicated tasks.

50 In practice, building a true heterogeneous SOA for a wide range of operating environments may take years of

51 development time if the company does not have sufficient SOA experience and expertise [4]. It is difficult to

52 foresee and justify the cost and effort of developing an SOA application before the project starts. The problem

53 of SOA cost estimation has not been addressed adequately in the existing literature.

54 2 A

The current cost estimation approaches for traditional software development are inadequate for complex service-55 oriented software. For example, COCOMO II cannot arrive at global cost approximation for the entire SOA 56 application development, and expert judgment may easily fall into traps of uncertainty or bias because of the 57 complexity of the SOA. This paper proposes a novel framework by employing a Work Breakdown Structure (WBS) 58 approach in an attempt to deal with cost estimation problem for SOA based software development. Within this 59 WBS framework, services are classified into three primitive types and one combined type according to different 60 development processes. Cost estimation for developing primitive services can be handled as sub-problems that 61 are small and independent enough to be solved. For combined services, the division procedure will emerge 62 recursively until all the resulting separated services are primitive. The cost and effort of service integration is 63 then calculated gradually following the reverse division sequence. The application of the WBS cost estimation 64 framework is demonstrated using a case study. The result shows that the proposed framework can simplify 65 and regulate the complicated development cost estimation for SOA-based applications. The business goals and 66 objectives of SOA are to increase agility and reduce costs while the technical goals and objectives are to increase 67 usability, improve maintainability and reduce redundancy [5]. SOA hold out the promise for a brave new world 68 of applications development, deployment, and reuse that many proponents believe will usher in unprecedented 69 levels of Return on Investment (ROI) for a domain that has long suffered from cost overruns and excessive, often 70 unjustified expenditures. The ability to lower the cost of integration while improving the leveragability of key 71 software and business process assets are only a few of the reasons why the ROI of service-oriented architectures 72 and composite applications is thought to herald a new economic reality for IT and business development. Ease 73 74 of use and lower training costs, lower cost of deployment, faster time to market, improved business requirement matching, and better multi-channel deployment are among the myriad reasons the technologies are so eagerly 75 awaited by business and IT managers alike. 76

77 **3 II.**

78 4 RELATED WORK a) SOA Services

SOA is a collection of services with well-defined interfaces and a shared communications model. A service 79 is a coarse-grained, discoverable, and self contained software entity that interacts with applications and other 80 services through a loosely coupled, often asynchronous, message-based communication model [6]. A system or 81 application is designed and implemented to make use of these services. This developed capability may itself 82 provide services within the overall SOA. The underlying idea of SOA is that it would be cheaper and faster 83 to build or modify applications by composing them out of limited-purpose components that can communicate 84 with each other because the components strictly adhere to interface rules [7]. The advent of the Internet and 85 World Wide Web (WWW) introduced a new wave of research on collaborative product development environment 86 ??8][9][10] ??11][12]. Yusuf et al., [13] Observed that the Internet is no longer a simple network of computers but a 87 network of potential services in which the functional views of services need to be clearly defined during the design 88 of an Internet-based distributed engineering system. The most common form of SOA is that of Web services 89 in which all of the following apply: service interfaces are described using Web Services Description Language 90 (WSSL), payload is transmitted using Simple Object Access Protocol (SOAP) over Hypertext Transfer Protocol 91 (HTTP), and Universal Description, Discovery and Integration (UDDI) is optionally used as the directory service 92 [14]. However, WSSL, SOAP, and HTTP are not the only foundation on which an SOA can be built. Other 93 technologies such as CORBA and IBM's Web sphere can be used as part of the messaging backbone of an SOA. 94

⁹⁵ 5 b) Work Breakdown Structure

A Work Breakdown Structure (WBS) is a hierarchical decomposition (tree structure) of the work required to accomplish a goal. It is developed by starting with the end objective and successively redividing it into manageable components in terms of size, duration, and responsibility [15]. However, it is often done as a modification of an existing WBS for a similar project. It is an essential starting input to both estimation and to scheduling.

In essence, it provides the chart of accounts for a project. To know what something cost, it needs to exist as 100 a task in the WBS. In large projects, the approach is quite complex and can be as much as five or six levels 101 deep. Usually, items at the same level of hierarchy are in the order they are executed, although this is not 102 required. Traditionally, definition of the WBS is left to vendors with the integrated master schedule and price 103 proposal based upon it included as part of the RFP response. More often than not, the organization of the 104 WBS in software development follows the traditional "waterfall" method of system development. The primary 105 constraint is that the WBS fulfils the requirements of the statement of work [16]. Since the development of 106 the software within services is about the same as traditional development, we suggest Breakdown of SOA into 107 Services from a WBS perspective. c) COCOMO II COCOMO II (Constructive Cost Model) [17] is one of 108 the best-known and best-documented algorithmic models, which allows organizations to estimate cost, effort, 109 and schedule when planning new software development activities. Tansey and Stroulia [18] have attempted to 110 use COCOMO II to estimate the cost of creating and migrating services. They reported that COCOMO II 111 should be extended to accommodate new characteristics of SOA based development. COCOMO II is generally 112 inadequate to accommodate the cost estimation needs for SOA-based software development. When considering 113 the declarative composition specifications, a fundamentally different development process may be adopted in 114 SOA-based software. Based on the Internet technologies, SOAbased software can be realized as a composition of 115 116 loosely coupled services with well-defined interfaces and consistent communication protocols. These services hide 117 technical details, and are not restricted to any specific technology. In other words, the service implementation is programming language and platform independent. Therefore, an SOA-based application could comprise the 118 combination of all possible development strategies and development processes. Consequently, although the 119 COCOMO II model has a large number of coefficients such as effort multipliers and scale factors, it is difficult 120 to directly justify the cost estimation for SOA-based software development. On the other hand, considering 121 the difference between component orientation and service orientation [19], the COCOMO II model by itself is 122 inadequate to estimate effort required when reusing service-oriented resources. COCOMO II considers two types 123 of reused components, namely black-box components and whitebox components. Black-box components can be 124 reused without knowing the detailed code or making any change to it, while white-box components have to be 125 modified with new code or integrated with other reused components before it can be reused. Similarly, within the 126 SOA framework, there are black-box services that can be adopted directly, and white-box services that should 127 be ported from legacy systems. Nevertheless, taking black-box reuse for instance, the difference between code-128 level and service-level reuse is significant. Whether a code-level component is suitable or not for reuse should 129 be understood and revealed by using reverse engineering or reengineering [20] according to the real situation. 130 Comparatively, the contractually reusable and loosely coupled service can be reused directly through service 131 discovery techniques, for example semantic annotation and quality of service. 132

¹³³ 6 d) Function Point Analysis and Software Sizing

Size prediction for the constructed deliverables has been identified as one of the key elements in any software 134 project estimation. SLOC (Source Line of Code) and Function Point are the two predominant sizing measures. 135 Function Point measures software system size through quantifying the amount of functionality provided to the 136 user in terms of the number of inputs, outputs, inquires, and files. In practice, Function Point can be used 137 continuously throughout the entire software development life cycle, which provides the essential value of what 138 the software is and what it does with data from the user's viewpoint. Santillo attempts to use the Function 139 Point method to measure software size in an SOA environment [21]. After comparing the effect of adopting 140 the first and second generation methods, that is the International Function Point User's Group (IFPUG) and 141 Common Software Measurement International Consortium (COSMIC) respectively, Santillo identifies several 142 critical issues. The prominent one is that SOA is functionally different from traditional software architectures, 143 because the "function" of a service should represent a real-world self-contained business activity [2]. More issues 144 appear when applying IFPUG to software system size measurement. For example, the effort of wrapping legacy 145 code and data to work as services cannot be assigned to any functional size. Measuring with the COSMIC 146 approach, on the contrary, is supposed to satisfy the typical sizing aspects of SOA-based software. However, 147 there is a lack of guidelines for practical application of COSMIC measurement in SOA context. In addition to 148 the application of Function Points, Liu et al. [22] use Service Points to measure the size of SOA-based software. 149 The software size estimation is based on the sum of the sizes of each service. 150

Where P i is an infrastructure factor with empirical value that is related to the supporting infrastructure, technology and governance processes; P represents a single specific service's estimated size that varies with different service types, including existing service, service built from existing resources, and service built from scratch. This approach implies that the size of a service-oriented application depends significantly on the service type. However, the calculation of P for various services is not discussed in detail.

¹⁵⁶ 7 e) SMART and SMAT-AUS Framework

The "Service-Oriented Migration and Reuse Technique" (SMART) was developed to assist organizations in analyzing legacy capabilities for use as services in an SOA. SMART was derived from the Options Analysis for Reengineering (OAR) method developed at the SEI that was successfully used to support analysis of reuse potential for legacy components [23]. SMART gathers a wide range of information about legacy components, the target SOA, and potential services to produce a service migration strategy as its primary product. However, SMART also produces other outputs that are useful to an organization whether or not it decides on migration.

Information-gathering activities are directed by the Service Migration Interview Guide (SMIG). The SMIG 163 contains questions that directly address the gap between the existing and target architecture, design, and code, 164 as well as questions concerning issues that must be addressed in service migration efforts. Use of the SMIG 165 assures broad and consistent coverage of the factors that influence the cost, effort, and risk involved in migration 166 to services. Unlike SMART, SMAT-AUS [24] is a framework that is developed to determine the scope and 167 estimate cost and effort for SOA projects. [25] that can be adopted for service mining cost estimation, currently 168 there are no other metrics suitable for the different projects beneath the SMAT-AUS framework. Instead, some 169 abstract cost-estimation-discussions related to aforementioned project types can be found through a literature 170 review. Umar and Zordan [26] warn that both gradual and sudden migration would be expensive and risky so 171 that costs and benefits must be carefully weighed. Bosworth [27] gives a full consideration about complexity 172 and cost when developing Web services. Liu et al. [22] directly suggest that traditional methods can be used to 173 estimate the cost of building services from scratch. Since utilizing solutions based on interoperable services is 174 part of service-oriented integration (SOI) and results in an SOI structure, Erl [28] gives a bottom line of effort 175 176 and cost estimation for cross-application integration: "The cost and effort of cross-application integration is significantly lowered when applications being integrated are SOAcompliant." A generic SOA application could 177 be sophisticated. But this can be handled in SMAT-AUS by breaking the problem into more manageable pieces 178 (i.e. a combination of project types) however specifying how all of these pieces are estimated and the procedure 179 required for practical estimation of software development cost for SOA-based systems is still being developed. 180

f) ROI of SOA Based on Traditional Component Reuse Barry Boehm provided two useful formulas when 181 estimating the cost of software systems reuse. One formula is from the provider's point of view, while the other is 182 from consumer's [29] Poulin Jeffery [30] examined large-scale SOA service providers to estimate the value ranges 183 for these formulas in practice. His data shows that RCWR ranges between 1.15 and 2.0 with median of 1.2, while 184 RCR ranges between 0.15 and 0.80 with a median of 0.50. In other words, Paulin work suggests that creating 185 reusable software component for a broad audience takes more resources (15% to 100% more) than creating a less 186 generic point solution. The 20% of the total cost of development directed towards reuse, a factor Poulin calls 187 Relative Cost of Reuse (RCR) would represent an impressive number in the pre-object-oriented development 188 world, but in the world of service oriented architectures and component application; it is believed that 80% is a 189 more accurate figure. This ability to reuse the majority of the software development by an organization is one of 190 the key attributes of SOA development, and while the number will vary greatly from one development organization 191 to another, it is our believe that the early adopters will see this or an even greater degree of reuse simply because 192 initial SOA development will target precisely those applications and business processes that have the greater 193 reuse potential. Mili et al., [31] has published a variety of RCWR factor values that have been developed since 194 the early 1990's based on the experiences of a number of sources. Discussion about cost estimation for SOA 195 implementation also appears in industry. Linthicum [32] outlines some general guidelines for estimating the cost 196 of an SOA application. According to these guidelines, the calculation of SOA cost can be expressed as a sum of 197 several cost analysis procedures. 198

Cost of SOA = (Cost of Data Complexity + Cost of Service Complexity +Cost of Process Complexity + 199 Enabling Technology Solution) Furthermore, Linthicum also provides some detailed specification. For example, 200 the basic element Complexity of the Data Storage Technology is figured as a percentage between 0% and 100% 201 (Relational is 30%, Object-Oriented is 60%, and ISAM is 80%). Nevertheless, the other aspects of the calculation 202 are suggested to follow similar means without clarifying essential matters. Meanwhile, Linthicum reminds that 203 the notable problem is that this approach is not a real WBS approach is a "Division of labour" or "Divide and 204 conquered" method which can be traced back to as early as 200BC [33], when the Babylonian reciprocal table 205 of Inakibit-Anu was used to facilitate searching and sorting numerical values. However, the first description of 206 the divide and conquered algorithm appears in John Mauchly's article discussing its application in computer 207 sorting [33]. Nowadays, the approach is applied widely in areas such as Parallel Computing [34], Clustering 208 Computing [35], Granular Computing [36], and Huge Data Mining [37]. The principle underlying WBS is shown 209 in Figure 1. That is to recursively decompose SOA into sub problems (services) until all the sub-problems are 210 sufficiently simple enough, and then to solve the sub-problems (cost the services). Resulting solutions (costs) 211 are then recomposed to form an overall solution. Adopting this principle will lead to different subroutines for 212 different sub-problems. Normally, some or all of the subproblems are of the same type as the input problem, thus 213 WBS procedure can be naturally expressed recursively. The QuickSort [33] algorithm has such The advantages 214 of applying WBS approach to SOA problems are numerous, and can be classified as followings: 215

? Structural Simplicity : Profiting from perhaps the simplest structuring technique, WBS is a high priority strategy to resolve problems not only in the SOA field but also in computing generally, politics and sociology fields. No matter where the approach is applied the solution structure can be expressed explicitly in a program-like function such as: Solution(x) is equivalent to: IF IsBase(x) Then SolveDirectly(x) Else Compose(Solution(Decompose(x)))

Where x is the original problem that will be solved through Solution procedure, IsBase is used to verify whether the problem x is primitive or not, which returns TRUE if x is a basic problem unit, or FALSE otherwise. Solve Directly presents the conquer procedure. Decompose is referred to as the decomposing operation, while Compose is referred to as the composing operation

? Computational Efficiency : WBS can be used for designing fast algorithms. In appropriate application 225 scenarios, the approach leads to asymptotically optimal cost for solving the problems. A problem of size N can 226 be broken into a bounded number P of sub-problems of size N/P step by step, and all the basic sub-problems 227 have constant-bounded size. Then the algorithm will have O(NlogN) worst-case program execution performance. 228 Normally, the consequence is more flexible because the size and the number of tasks can be decided at run-time. 229 ? Parallelism : Since sub-problems in the individual division stage are logically and physically independent, 230 the WBS approach can be naturally executed in parallel procedures. For computing problems, it is suitable for 231 application in parallel machines due not only to the independent problem grains but also the efficient use of cache 232 and deep memory hierarchies [38]. In fact, it has been considered as one of the well-known parallel programming 233 paradigms. 234

235 ? Capability of Solving Complexity : Through Dismantle of an overall goal into smaller and independent 326 sub-problems, the SS strategy can provide adaptation scalability and variability, and can be used in the areas 327 of engineering to reduce and manage complexity. Those complicated cases, such as resolutions for conceptually 328 difficult problems, and approximate algorithms for NP-hard problems, are usually based on the divide and 329 conquer principle. Given these merits, WBS can be considered a suitable and effective approach to accommodate 320 complex problems such as cost estimation for SOA-based software development, where individual measures must 321 be carried out independently. The following sections discuss its applications in SOA cost estimation.

242 procedure.

²⁴³ 8 b) Service Classification

Implementing SOA could be complex and onerous, while complexity measurement for SOA-based system is 244 still an open question [39]. Chaos [40] claims that the complexity is restricting some SOA implementations. 245 For the same reason, there are also many challenges to estimate the cost and effort of SOAbased software 246 development. Fortunately, the major advantages of SOA are mainly reusability and composability with an 247 emphasis on extensibility and flexibility, at a high level of granularity and abstraction. In other words, SOA-248 based software can be naturally divided into a set of loosely coupled services. These services can then be 249 classified through their different features. Krafzig et al. [41] has identified that distinguishing services into 250 classes is extremely helpful when properly estimating the implementation and maintenance cost, and the cost 251 factors may vary depending on the service type. However, there is no standard way to categorize services. Service 252 classification can be different for different purposes, for example differentiating services according to their target 253 audience [2], categorizing services through their business roles and responsibilities [28], and classifying services 254 by using their background techniques and protocols [42]. Services in our work are characterized as follows: 255

256 ? Available Service (basic service type), when the service already existing i.e. it may be provided by a third 257 party or inherited from legacy SOA based systems.

? Migrated Service (basic service type), is the service to be generated through modifying or wrapping reusable
 traditional software component(s).

260 ? New Service (basic service type), is the service to be developed from scratch.

261 ? Combined Service is the service arising from the combination of any above three types of basic services or 262 other combined services.

Through this type of classification, four different development areas are identified in SOA projects. These areas present both a decomposition process that results in Service Discovery, Service Migration, and Service Development, and a recomposition process that is Service Integration. The cost estimation for overall SOAbased software development can then be separated into these smaller areas with corresponding metrics. Therefore, the WBS approach is a feasible attempt for SOA-based software cost estimation following this development oriented service classification.

²⁶⁹ 9 c) WBS Cost Estimation Frameworks

The proposed cost estimation framework for SOA-based software follows the WBS principle. Firstly, through 270 the service-oriented analysis, the SOA project is divided into basic services recursively. Secondly, different sets 271 of metrics are adopted to satisfy the cost and effort estimation for different service development processes. The 272 total cost and effort of the SOA project will be calculated through the service integration procedure as shown in 273 274 Figure 2. C1 is the cost estimation model or software size measurement used to accomplish modelling or sizing 275 work for discovering available services, C2 represents migrating potential services, C3 represents developing new 276 services, and C4 is the cost estimation model or size measurement for calculating the service integration effort. 277 The Decomposability condition depends on the design and real situations whether the current service should be further divided or developed as a whole. The framework in Figure 2 presents the generic process of SOA cost 278 estimation using the WBS method. To precisely describe the WBS based cost estimation for SOA-based software 279 development, the complete process was expressed in pseudo code (Table ??). We define the stage that service 280 division occurs as the service levels, and the combined service stands in a higher level next to its successive 281 component services. 282

283 10 MPLEMENTATION

We employ Visualization RCD Beam for Service Oriented Architecture (VisRCDBeam for SOA) implemented by Yusuf et al [43] as an application case study. There are two reasons for choosing this case:

The VisRCDBeam for SOA case study characterizes all the service types listed in the previous section, and there are a limited number of services which are adequate for illustrative purpose in this paper.

The SOA project itself is treated at the highestlevel coarse-grain service, which is also the initial input parameter of SoaCostEstimation function. Within the body of SoaCostEstimation function, the cost of the input service development will be estimated directly if the service belongs to those three basic types, or recursively calculated by analyzing and composing the cost and effort of the development for component services.

When composing individual service development costs into the overall SOA-based software development cost, 292 the strategy of supposed service integration is progressed level-by-level instead of integrating the services all at 293 once. The reason of adopting such a strategy is that, according to our work, service integration occurring in 294 different levels will make different contributions to the total cost and effort of the project development. A real 295 example can be used to by using corresponding metrics C3. f. Estimate the cost and effort of integrating the above 296 four component services into the VisRCDBeam for SOA Service by using corresponding metrics C4. g. Divide 297 the VisRCDTable Advisor Service into its two basic component services. h. Notice that Legacy System Service 298 (i.e., RCDBeam) and Transform Service (i.e., RCD Table ?? have both been taken into account. i. Estimate the 299 cost and effort of mining the Legacy System Service (i.e., RCDBeam) and Transform Service (i.e., RCD Table) by 300 using corresponding metrics C1. Since these two services are in the same project and can be directly identified, 301 the cost and effort here can be treated as zero in this special case. j. Estimate the cost and effort of integrating 302 the above two component services into the VisRCDTable Advisor Service by using the corresponding metrics 303 C4. k. Estimate the cost and effort of integrating the VisRCDBeam for SOA Service and VisRCDTable Advisor 304 Service into the Automation System by using the corresponding metrics C4. I. Sum up all the estimation results 305 to calculate the total cost and effort of the Automation System development. Through the demonstration of the 306 307 VisRCDBeam for SOA case, the WBS framework is proven helpful for simplifying and regulating the SOA-based 308 software cost estimation. Moreover, all the simplified cost estimation problems are independent enough to be solved in parallel. The uniform and explicit working procedure within this WBS framework is then a feasible 309 attempt to SOA based software cost estimation. 310

311 **OA ENEFITS**

SOA benefit organizations in different ways, depending on the respective goals and the manner in which SOA is applied. We have generalized the list of common benefits and certainly not exhaustive. It is merely an indication of the potential this architectural platform has to offer.

³¹⁵ 12 Improved integration (and intrinsic interoperability)

SOA can result in the creation of solutions that consist of inherently interoperable services. The net result is intrinsic interoperability, which turns a crossapplication integration project into less of a custom development effort, and more of a modeling exercise. The cost and effort of cross-application integration is significantly lowered when applications being integrated are SOA-compliant.

320 13 Inherent reuse

Service-orientation promotes the design of services that are inherently reusable. Building services to be inherently reusable results in a moderately increased development effort and requires the use of design standards. Subsequently leveraging reuse within services lowers the cost and effort of building serviceoriented solutions.

³²⁴ 14 c) Streamlined architectures and solutions

The concept of composition is another fundamental part of SOA. It is not, however, limited to the assembly 325 of service collections into aggregate services. The WS platform is based in its entirety on the principle of 326 composability. This aspect of service oriented architecture can lead to highly optimized automation environments, 327 where only the technologies required actually become part of the architecture. Realizing this benefit requires 328 adherence to design standards that govern allowable extensions within each application environment. Benefits 329 of streamlined solutions and architectures include the potential for reduced processing overhead and reduced 330 skill-set requirements (because technical resources require only the knowledge of a given application, service, or 331 service extension). 332

³³³ 15 d) Leveraging the legacy investment

The industry-wide acceptance of the Web services technology set has spawned a large adapter market, enabling many legacy environments to participate in service-oriented integration architectures. This allows IT departments to work toward a state of federation, where previously isolated environments now can interoperate without requiring the development of expensive and sometimes fragile point-to-point integration channels. Though still riddled with risks relating mostly to how legacy back-ends must cope with increased usage volumes, the ability to use what we already have with service-oriented solutions that we are building now and in the future is extremely attractive. The cost and effort of integrating legacy and contemporary solutions is lowered. The need for legacy

341 systems to be replaced is potentially lessened.

³⁴² 16 e) Establishing standardized XML data representation

On its most fundamental level, SOA is built upon and driven by XML. As a result, an adoption of SOA leads 343 to the opportunity to fully leverage the XML data representation platform. A standardized data representation 344 format (once fully established) can reduce the underlying complexity of all affected application environments. 345 Past efforts to standardize XML technologies have resulted in limited success, as XML was either incorporated 346 in an ad-hoc manner or on an "as required" basis. These approaches severely inhibited the potential benefits 347 XML could introduce to an organization. With contemporary SOA, establishing XML data representation 348 architecture becomes a necessity, providing organizations the opportunity to achieve their goal, the cost and 349 effort of application development is reduced after a proliferation of standardized XML data representation is 350 achieved. 351

352 **17** S B

353 V.

"Best-of-breed" alternatives Some of the harshest criticisms laid against IT departments are related to 354 the restrictions imposed by a given technology platform on its ability to fulfill the automation requirements of 355 an organization's business areas. This can be due to the expense and effort required to realize the requested 356 automation, or it may be the result of limitations inherent within the technology itself. Either way, IT departments 357 are frequently required to push back and limit or even reject requests to alter or expand upon existing automation 358 solutions. SOA won't solve these problems entirely, but it is expected to increase empowerment of both business 359 and IT communities. A key feature of service-oriented enterprise environments is the support of "best-ofbreed" 360 technology. Because SOA establishes a vendorneutral communications framework, it frees IT departments from 361 being chained to a single proprietary development and/or middleware platform. For any given piece of automation 362 363 that can expose an adequate service interface, we now have a choice as to how we want to build the service that implements it. The potential scope of business requirement fulfillment increases, as does the quality of business 364

365 automation.

³⁶⁶ 18 h) Organizational agility

Agility is a quality inherent in just about any aspect of the enterprise. A simple algorithm, a software component, 367 a solution, a platform, a process all of these parts contain a measure of agility related to how they are constructed, 368 positioned, and leveraged. How building blocks such as these can be realized and maintained within existing 369 370 financial and cultural constraints ultimately determines the agility of the organization as a whole. Much of serviceorientation is based on the assumption that what you build today will evolve over time. One of the primary 371 benefits of a welldesigned SOA is to protect organizations from the impact of this evolution. When accommodating 372 change becomes the norm in distributed solution design, qualities such as reuse and interoperability become 373 commonplace. The predictability of these qualities within the enterprise leads to a reliable level of organizational 374 agility. However, all of this is only attainable through proper design and standardization. Change can be 375 disruptive, expensive, and potentially damaging to inflexible IT environments. Building automation solutions 376 and supporting infrastructure with the anticipation of change seems to make a great deal of sense. A standardized 377 technical environment comprised of loosely coupled, composable, and interoperable and potentially reusable 378 services establishes a more adaptive automation environment that empowers IT departments to more easily 379 adjust to change. Further, by abstracting business logic and technology into specialized service layers, SOA can 380 establish a loosely coupled relationship between these two enterprise domains. This allows each domain to evolve 381 382 independently and adapt to changes imposed by the other, as required. Regardless of what parts of serviceoriented environments are leveraged, the increased agility with which IT can respond to business process or technology-383 related changes is significant. The cost and effort to respond and adapt to business or technologyrelated change 384 is reduced. 385

386 19 VI.

387 20 DISCUSSION

388 The aim of visRCDBeam for SOA is to upgrade its automation system so that it could remain competitive with 389 other RCD tools and continue its business relationship with its primary client. We proceeded with a service-390 oriented analysis that decomposed its business process logic into a series of service candidates. This revealed the need for the following potential services and service layers: (a) A business service layer consisting of two 391 tasks centric business services namely visRCDBeam for SOA and VisRCDTable Advisor, (b) An application 392 service layer comprised of four application services. Each business process was represented with a task-centric 393 business service that would act as a controller for a layer of application services. Reusability and extensibility 394 in particular were emphasized during the design of the application services. We intend to have the initial SOA 395

to consist of services that supported both of its current business processes, while being sufficiently extensible 396 to accommodate future requirements without too much impact. To realize the visRCDBeam for SOA tool, we 397 compose these services into a two-level hierarchy where the parents VisRCDBeam for SOA and VisRCDTable 398 advisor business services coordinate the execution of all application services. Unlike many of the current cost 399 estimation approaches, the proposed WBS framework uses a set of metrics to satisfy the development cost 400 estimation for SOA-based software. The WBS concentrates on the software development process. It list Service 401 Discovery as an individual cost estimation area as well as Service Migration, Service Development, and Service 402 Integration. The framework estimates overall cost and effort through the independent estimation activities in four 403 different development areas of an SOA application. WBS framework is generic and flexible by switching different 404 types of metrics; it could satisfy different requirements of SOA-based software cost estimation such as building 405 cost estimation model, measuring software size, and predicting the overall cost ultimately. One issue is that 406 there are currently few available metrics for the detailed cost estimation for SOA-based software development. 407 Future research should develop new metrics to resolve this issue. Meanwhile, some reusable existing metrics 408 can be integrated into the proposed WBS framework, for example Tansey and Stroulia's work [18] [related to 409 Service Development and SMART method [26] are related to Service Migration. Over all, instead of trying 410 to enumerate SOA project types, the WBS framework unifies and regulates the cost and effort estimation for 411 412 SOA-based software development.

413 **21 VII.**

414 22 CONCLUSION

Poor project management could bring failure to SOA. Gone are the days when one person is the SOA architect, 415 developer, data architect, network architect and security specialist. The complexity of SOA should not be 416 underestimated. Failure to implement and adhere to SOA governance is an imperative issue; the development 417 effort is shifting from building services to consuming services. Vendors could be allowed to drive the architecture 418 but relying too much on vendors can be a disaster. Conquer theory, this framework can be helpful for simplifying 419 420 the complexity of SOA cost estimation. By hosting different sets of metrics, this generic framework will be suitable 421 not only for the complete cost estimation work but also for the partial requirements, such as building estimation model, and measuring the size of SOA applications. We have fulfilled our original goals by producing proper 422 423 costing of an SOA project that supports two service-oriented solutions. Online transaction is now possible. New requirements can be accommodated with minimal impact. The standard application service layer will 424 likely continue to offer reusability functionalities to accommodate the fulfilment of new requirements. And 425 any functional gaps will likely be addressed by extending the services without significantly disrupting existing 426 implementations. Furthermore, should we decide to replace our taskcentric business services with an orchestration 427 service layer in the future, the abstraction established by the existing application service layer will protect the 428 application services from having to undergo redevelopment. We have established a legacy system service (which 429 is essentially a wrapper service for graphics drawing) as part of its application service layer it has opened up a 430 generic and point that can facilitate integration. There is an old saying that you cannot manage what you cannot 431 measure. By increasing the number of "moving pieces" in IT solutions, SOA increases the number of pieces that 432 require measurement. Given the relative immaturity of the SOA paradigm, it is particularly important now, 433 434 when best practices have not yet been established and the understanding of cause and effect is limited. Indeed, the inability to collect cost and schedule data at the task level may be part of the reason why so many case 435 studies in SOA only present project-level estimates of averted cost.
